Optical isomers are often said to be identically alike in their chemical properties; but this is not rigorously true. The resemblance is

Pasteur separated racemic acid into its constituents by neutralizing it with cinchonine, separating the respective salts by crystallization, and then decomposing the respective cinchonine salts so as to liberate the two active varieties of tartaric acid. Ordinary lactic acid may be separated into its constituents by making use of the different solubilities of the lactates of zinc. (2) Certain microscopic organisms affect the various isomeric forms in different ways. Thus the mold fungus, *Penicillium glaucum*, when allowed to act upon a dilute solution of ammonium racemate, destroys the dextro-rotatory tartaric acid, while leaving the lævo-rotatory variety unaffected. (3) Sometimes the compounds of the dextro-rotatory and lævo-rotatory isomers crystallize in separate enantiomorphous crystals, from which the crystals of one type can be picked out by hand. This method was used by Pasteur with success in the case of sodium-ammonium racemate; but it is not of very general applicability, because the isomeric salts usually separate out together, in one mass.

In conclusion it may be well to say that it is not at all probable that the atoms of carbon compounds are actually arranged in space in accordance with the geometric representations that are adopted in stereo-chemical theory. The tetrahedron diagrams are exceedingly useful for representing the chemical facts as we know them in the laboratory; but we know very little and perhaps nothing, of the actual way in which the atoms of compounds (whether

carbon compounds or not) are arranged in space.

Consult Van't Hoff, 'Stereochemie,' and 'Dix années dans l'histoire d'une théorie'; Hantzsch, 'Grundriss der Stereochemie'; and Nernst, 'Theoretical Chemistry,' together with the references therein given.

ALLAN D. RISTEEN.

STEREOCHROMY, in art, a process of mural painting in which water glass is used to fix or consolidate the colors. See PAINTING, TECHNIQUE OF.

STEREOGRAM, Parallax, a novel photographic transparency, the invention of Frederic E. Ives, which, without a stereoscope or other optical aid, shows the objects photographed in full stereoscopic relief, when viewed from a certain point, directly in front. It consists of (1) a single photograph on glass which is a composite in alternate fine vertical lines of the two halves of an ordinary stereogram, and (2) of an opaque line cover screen mounted upon it, with a separation of about thirty one-thousandths of an inch. The relative disposition of the lines of the photograph and those of the cover screen is such that by parallax of vision, each eye sees those lines and only those which make up the image belonging to that eye. They can be so made as to show the objects apparently standing in the air, either through and beyond the glass or between the glass and the eyes. The large size of the photographs and the absence of any visible optical aid make the results more realistic and impressive than by other means of stereoscopic representation.

STEREOGRAPHIC PROJECTION, a name given that projection of the sphere which is represented on the plane of one of its great circles, the eye being situated at the pole of that great circle. All circles are projected either into straight lines or circles, and the angle made by two circles meeting on the globe is the same as that made by the projections of those circles. It is the projection generally employed in ordinary atlases. The distortion in the form of countries on the plane surface is very slight.

STEREOPTICON, a name given to a combination of two or three magic lanterns or optical lanterns arranged so as to focus in the same circle of light on the screen, for the production of what are termed "dissolving views." The views are "dissolved" one into another by alternately throwing pictures from the two lanterns, the one gradually taking form while the picture from the other gradually fades upon the screen. With the oxy-hydrogen or calcium light the dissolving effect is produced by switching the gas from one lantern to the other. With the electric light it is done by revolving a shutter in front of the projecting lenses of the lanterns. This effect is much more beautiful with the calcium light, as the lime loses its brilliancy in the one lantern and acquires it in the other by degrees, the one view "melting" into the other. With the shutter the transformation is perceptible in a very unpleasant "winking" movement. Where the third lantern is added it is used independently to throw a second image upon a picture already on the screen, as in the case of a vision or dream, ghost or other phantas-

magoria. It may also be used to tint delicately the view on the screen. See MAGIC LANTERN; OPTICAL LANTERN.

STEREORITHES, stě-rě-ôr-nî-thěz, a group of extinct birds of gigantic size, remains of which are found in Patagonia in the Miocene Age strata. They were distantly related to the herons and to the *Seriema*. The head was large with a high and powerful beak, and the palate was desmognathous.

STEREOSCOPE, an optical apparatus which enables us to look at one and the same time upon two photographic pictures nearly the same, but taken under a small difference of angular view, each eye looking upon one picture only; and thus, as in ordinary vision, two images are conveyed to the brain which unite into one, the objects being thus represented under a high degree of relief. The stereoscope is constructed in accordance with the visual phenomena which convey to the mind impressions of the relative forms and positions of an object. When a near object having three dimensions is looked at, a different perspective representation of it is seen by each eye; in other words, there is distinct binocular parallax. Certain parts are seen by the right eye, the left being closed, that are invisible to the left eye, the right being closed and vice versa, and the relative positions of the portions visible to each eye in succession differ. These two visual impressions are simultaneously perceived by both eyes, and are combined into one image, producing the impression of perspective and relief. If, then, truthful right-and-left monocular pictures of any object be so presented to the two eyes that the optic axes, when directed to them, shall converge at the same angle as when directed to the object itself, a solid image will be seen. This is effected with the stereoscope, a reflecting form of which was invented by Professor Wheatstone in 1838. It is constructed so that the two dissimilar pictures are reflected to the eyes from two small plane mirrors placed at right angles, the faces being toward the observer. Subsequently Sir David Brewster invented the refracting or lenticular stereoscope, based on the refractive properties of semi-double convex lenses; and this instrument, of which there are numerous forms, is now in general use. Convex lenses magnify the pictures besides producing a stereoscopic effect. Photography greatly assists the stereoscope in providing perfectly accurate right-and-left monocular views, which are taken simultaneously on a plate in a twin camera. Sometimes, in the case of objects which from their distance have no sensible binocular parallax, photographs are taken from two points considerably apart; and when such views are combined in the stereoscope the effect of relief is greatly exaggerated. A most interesting application has been made of this principle to the photography of comets, the position of the observer between the two exposures being greatly changed owing to the fact that the earth on which he stands is continually moving about the sun with a speed of more than 18 miles a second. Though the results are somewhat marred by the fact that the comet itself is moving, and also changing its shape, yet when the two pictures are combined, the stereoscopic effect is in many cases beautifully shown.

Several modifications of the reflecting stereoscope are distinguished by the names pseudoscope, iconoscope, telestereoscope and polis-tereoscope, the last being an apparatus which serves the purposes of all the others. See CAMERA; LIGHT.

STEREOSCOPIC SLIDE, a slip of cardboard on which are mounted side by side two photographs of the same scene or object, intended to be viewed through a stereoscope. Theoretically, these photographs should be taken by similar lenses from points of view separated by a space equal to the distance between the human eyes, but in practice—especially in dealing with architectural groups—the space is increased in order to procure a greater effect.

STEREOTROPE, a mechanism by which an object is perceived as if in motion, and with an appearance of solidity or relief as in nature. It preceded and suggested the moving pictures. It consists of a series of stereoscopic pictures, generally eight, of an object in the successive positions it assumes in completing any motion, affixed to an octagonal drum, revolving under an ordinary lenticular stereoscope, and viewed through a solid cylinder pierced in the entire length by two apertures, which makes four revolutions for one of the picture drum. The observer thus sees the object constantly in one place, but its parts apparently in motion, and in solid and natural relief.

STEREOTYPE, a printing plate cast in soft metal from a plaster or papier-mâché mold, on which is a facsimile in reverse of a form of type, linotypes, cuts, etc., and which, when fitted to a block, may be used on a printing press exactly as movable type. For daily newspaper printing the stereotype is usually a curved plate, clamped directly on the surface of a printing cylinder. The stereotype process is rapid, but adapted only to coarse printing, the fine grades of printing requiring the electrotrope (q.v.). See AUTOPLATE.

STERILITY is a condition which may be present in either sex where from various types of disorder there is incapacity to reproduce the species. In the male sex the spermatozoa may be absent in the semen or if present may be diseased and incapable of impregnating the ovum of the female. A practical type of sterility may arise from impotence in the male, whereby the consummation of the reproductive act is impossible. This is not a real sterility cause, technically speaking, but is practically so for certain matings, for many males are impotent with certain mates and not so for others. (See IMPOTENCY). The chief causes which render the male sterile are either anatomical defect of the genital apparatus producing an obstruction to the discharge of semen or to some disease of the testicles themselves. Absence of the testicles, accidental or induced (eunuchs), is a rare cause. Various inflammations of the testicles such as gonorrhœal orchitis, mumps orchitis or other type of testicular inflammation may destroy the spermatozoa or reduce their viability. Syphilis is also a frequent cause for reducing the capacity of the spermatozoa to fecundate the ovum. A large group of rare conditions related to the glands of internal secretion may cause sterility. (See SYNDROMES, ENDOCRINOUS).

A peculiar accidental type of sterility occurs among individuals exposed frequently to X-ray emanations. Some of these emanations or rays of light of very high wave velocity have an action upon the testicles causing loss of power to manufacture spermatozoa or to cause a loss of their fecundating power. The development of spermatozoa is largely regulated by the nervous system, and there are certain individuals who permanently or periodically are unable from nervous (mental) disturbance to manufacture viable spermatozoa. Little is known of this important group but recent researches in psychopathology are revealing the relationships between faulty affective reactions (psychoses and psychoneuroses) and the proper metabolic activities of the body which make healthy spermatozoa. This is an extremely large group and is classed, in general, by psychopathologists under the broad head of compensating neuroses. Here the individual's over-compensatory affective striving for social potency may so disturb the endocrinous functions as to bring about the results just described. This psychogenic basis for sterility affects both male and female and is to be seen in many individuals who show such symptoms as unusually eccentric individuals either vocational, such as professional, religious, artistic, mechanical, commercial, philosophic striving: Exaggerated sexual strivings as seen in pimps, seducers, white slavers. Eccentric penitentials, reformers, reconstructionists, hyperconscious individuals, obsessional, occultists, mystics, divine inspirationists. These over-compensatory strivings are frequently obvious in eccentric food habits, exhibitionistic clothing, eccentric modesty, grandiloquents, etc. The affective cravings cause hypertension in the muscles, increased heart action, raised blood pressure, hyperactive adrenal glands, thyroid and liver activities and cause retrograde changes in the sex glands, thus impairing fecundity. This type of individual may be helped by the use of the organic endocrine extracts or by proper psychotherapy-psychoanalysis (q.v.).

In the female the causes for sterility are equally plentiful. These may be grouped as (1) failure of development of the ovary, uterus or other important parts of the reproductive apparatus. (2) Disease of the ovary, similar to diseases of the testicles, from syphilis, alcoholism, gonorrhœa, mumps and other inflammations. (3) Obstructions to the passage of the spermatozoa to the ovum or of the ovum to the uterus, the chief one of these is gonorrhœal disease of the fallopian tubes and is the one greatest single factor in causing sterility in the female. (4) Disease of the uterus lining membranes or of the vaginal membranes, causing changes in the chemisms of the secretions which destroy or weaken either the ovum or the spermatozoa or both. (5) The psychogenic factors already enumerated which may affect the vitality of the ovum through the nervous system mediated through the balance of endocrine function, or such affective disturbances can modify permanently or periodically the chemism of the vaginal or uterine secretions and destroy the viability of spermatozoa. Very minute variations in the chemistry of these secretions can prove disastrous to the viability of both ovum and spermatozoa.

In the determination of what factors may be operative in causing sterility of any given mating all of the factors enumerated may have to be investigated. The mechanical causes described are readily determined but the study of and amelioration of the psychogenic factors is extremely complicated and difficult. In the present state of knowledge many of these factors cannot be thoroughly comprehended. Consult 'American Textbook of Obstetrics for Mechanical Causes'; Falta, 'The Ductless Glands for Endocrine Disorders'; Kempf, 'The Autonomic Functions and the Personality for Psychogenic Mechanisms.'

SMITH ELY JELLIFFE, M.D.

STERILIZATION, in reference to human beings, an operation performed in order to deprive a man or woman of the power of reproduction. Many methods of sterilization might with greater propriety be termed asexualization, since they have certain harmful effects, both physical and mental. The general methods now employed are, in the male, vasectomy, or the removal of a portion of the seminal duct, and, in the female, salpingotomy, or the removal of a portion of the Fallopian tubes.

In the United States the sterilization of individuals is ordered by positive legal enactment for eugenic, punitive and therapeutic reasons. Indiana, in 1907, enacted the first sterilization law and Washington, California, Connecticut, Nevada, Iowa, New Jersey, New York, North Dakota, Michigan, Kansas and Wisconsin have since passed similar laws. The main object of such legislation is to prevent the procreation of habitual criminals, feeble-minded and insane persons. For an extended discussion of this subject, its advisability, the proper limitations, etc., consult Ellis, Havelock, 'The Sterilization of the Unfit' (in *Eugenics Review*, Vol. I, London 1909), and Laughlin, H. H., 'The Legal, Legislative, and Administrative Aspects of Sterilization' (in 'Eugenics Record Office, Bulletin No. 10B' (Cold Spring Harbor, N. Y., 1914).

STERILIZATION OF MILK. See MILK.

STERILIZED FOOD, any article of food which has been subjected to a sterilizing process that destroys the bacteria which cause fermentation and disease. Heat is the agent most commonly employed, and the process is more especially applied to milk. See FOOD PRESERVATION; MILK — *Pasteurization*.

STERLING, John, Scottish author: b. Kames Castle, Isle of Bute, 20 July 1806; d. Ventnor, Isle of Wight, 18 Sept. 1844. He was graduated from Cambridge in 1824 and had attained some prominence in the literary world of London before his editorship with Frederick Denison Maurice of the *Athenaeum* in 1828. In 1833 he published a novel, 'Arthur Coningsby,' and in 1839 'Minor Poems.' Three years later appeared 'The Election,' a poem, and 'Stratford,' a drama. His later work, accomplished during his years of declining health, includes also a series of prose poems published in *Blackwood's*, and eight cantos of 'Richard Cœur de Lion,' three of which were published posthumously in *Frazer's Magazine*, and were much praised by his friend, Carlyle. A collection of his essays and tales was published with a memoir by J. C. Hare in 1848. Consult

Carlyle, 'The Life of John Sterling' (1851); also letters of Sterling and Ralph Waldo Emerson, with sketch of Sterling's life by Edward Waldo Emerson (1897).

STERLING, Thomas, American public official: b. near Amanda, Fairfield County, Ohio, 21 Feb. 1851. In 1875 he was graduated at Illinois Wesleyan University, was admitted to the bar three years later and in 1880-81 was city attorney of Springfield, Ill. In 1882 he removed to Spink County, S. D., and from 1901 to 1911 was dean of the College of Law of the University of South Dakota, afterward resuming his law practice. Mr. Sterling was member of the first state senate of the South Dakota legislature in 1890, and in 1913 was elected to the Senate of the United States.

STERLING, Colo., city and county-seat in Logan County, on the South Platte River, 118 miles northeast of Denver, on the Union Pacific and the Chicago, Burlington and Quincy railroads. It has a sugar beet factory and is a trade centre for sugar beets, alfalfa and livestock. Pop. 3,044.

STERLING, Ill., city in Whiteside County; on the Rock River, and on the Chicago and Northwestern and the Chicago, Burlington and Quincy railroads, about 110 miles west of Chicago and 50 miles northeast of Rock Island. Electric lines connect the city with many of the nearby places. It was settled in 1834 by Hezekiah Brink; and founded as two places, Chatham and Harrisburg, in 1837. In 1839 they were consolidated, and on 16 Feb. 1857 organized as the village of Sterling. In 1872 it was reorganized under the Illinois general law. Sterling is in a fertile agricultural and rich dairy region, and its excellent water power contributes to its manufacturing advantages. The chief industrial establishments are farm implements, nuts and bolts, wire factories, gas engine works, condensed milk, ice cream, candy, hearse factories, pump factory, foundries, machine shops, buggy factory, silver plating and hardware works. There are about 3,000 employees. There are 14 churches, a township high school, three graded schools, one parish school and one business college. One State, one savings and two national banks have a combined capital of \$300,000. The government is commission form. Pop. (including Rock Fall) 13,000.

STERLING, Kans., town in Rice County, 225 miles west of Kansas City, on the Atchison, Topeka and Santa Fé and the Missouri Pacific railroads. Its industries comprise milling, grain elevators and salt making. There are three banks, with combined capital of \$150,000 and deposits aggregating \$600,000. The value of the taxable property is placed at \$2,183,000. Sterling is the seat of Cooper College and has a high school, city hall and library. The government is carried on through common council. The municipal receipts average yearly \$15,000. Pop. 2,300.

STERLING. A term used for the "standard" quality of English silver. The British sterling alloy proportion has varied at different times in the course of her history. For a long series of years the standard of silver (sterling) has been 11 ounces and two pennyweights of

chemically pure silver alloyed with 18 penny-weights of copper; which is 37 parts out of 40 pure silver and three parts of copper, or, as commonly expressed, 222 parts pure silver to 18 parts alloy. As to the derivation of the term sterling this is a long-standing topic for controversy. Numerically, the preponderance of opinion is in favor of the word being derived from the Anglo-Saxon *easterling* or *esterling*. Some writers describe the conditions thus: The merchants of the Hanseatic cities and the Netherlands produced a better coinage than the degraded English pieces and King John (early 13th century) called in the services of the coiners (*moneyers*), who were known as "easterlings" or men of the East, to use their proficiency at the English mint; and the coins so struck were termed *esterling* or *sterling*. Camden (16th century) derives the word from *easterling* or *esterling* and observes that the money brought from Germany, in the reign of Richard I (end of 12th century), was the most esteemed on account of its purity, being called in old deeds "nummi easterling." A statute of Edward I reads: "Denarius Angliæ qui vocatur sterlingas," etc. (which translated means "the penny of England, which is called sterling"). Du Cange, in 1733, wrote: "Esterlingus, sterlingus, are words relating to money, and hence familiar to other nations, and applied to the weight, quality, and kind of money." Documentary evidence informs us that the weight known as sterling was the equivalent of 32 grains of wheat. Pieces coined were double sterling, half sterling and quarter sterling. They were all of silver. The sterling *type* or face (see NUMISMATICS) consisted of a royal crowned head, some are full face, some are in profile; the *reverse* is "a large cross impaling the legend and is cantoned with 12 bezants." This mintage was copied in Scandinavia, Holland, Flanders, in northern France, on the Rhine and Westphalia. The English sterling *type* (face) remained constant for the gros, penny, half-penny and farthing from Edward I (1272) till Henry VII (1485), and was the national type. In the scale of weights also the pound sterling was standard. After the middle of the 16th century sterling *type* disappeared from the English coinage which retained the term sterling. The Saxon pound sterling was divided into 20 shillings at 12 pence each, so that there are 20 shillings to one pound sterling. In her colonial financing guineas came into use for a time but have since given way to the pound sterling as standard of coinage. Some writers have considered the derivation of the term coming from *star* because the coins had a cross carrying four sceptres on its arms and looking like a star. But there are so many sides and direct facts connected with the word sterling that a learned Frenchman, J. Chautard, wrote a large work on the subject without exhausting the stock of material in hand; it is entitled 'Imitations des Monnaies au Type Esterlin' (Published in Nancy in 1874).

CLEMENT W. COUMBE.

STERN, Louis, American merchant: b. Germany, 22 Feb. 1849. He received a common school education at Albany, N. Y., and removing to New York established the well-known department stores of Stern Brothers. He was the Republican candidate for president of the

borough of Manhattan in 1897, United States commissioner to the Paris Exposition of 1900, chairman of the executive committee, New York State commission to Louisiana Purchase Exposition (1904) and is president of the Republican Club. He is a member of the Metropolitan Museum of Art and of the American Museum of Natural History and president of the Hebrew Orphan Asylum.

STERNBERG, Constantin Ivanovitch Elder von, pianist, composer, educator and author: b. Saint Petersburg, Russia, 9 July 1852. He studied at the Leipzig Conservatory under Moscheles, Reinecke, Richter, Hauptmann and David in 1856-67; later under Kullak at the Berlin Academy of Music in 1872-74, also in Weimar and Rome under Liszt. Became conductor of operas in the Bruehl Theatre in Leipzig and assistant chorus master at the Municipal Theatre there from 1867 to 1869. In 1870 he conducted opera in Wurnburg, Kissingen and became conductor of the Court Theatre in Mecklenburg-Strelitz, 1873. Here intervened his study of the piano under Kullak and Liszt, and from 1875 to 1878 he was director of the Academic Music School and pianist to the Court at Mecklenburg-Schwerin, which positions permitted him to fill a large number of engagements for concerts in all the large music centres of Germany. In the following year his concert tours extended over the most of continental Europe, Russia, Asia Minor and part of central Asia, also northern Egypt. At the end of this tour he was summoned to play for Emperor William I, who distinguished him so markedly as to spread his fame across the ocean. He received and, after some hesitation due to his being engaged to marry, accepted an offer to play in the United States and Canada 100 concerts within five months. He was re-engaged season after season until 1886 his wife's ill-health obliged him to locate in the South (Atlanta, Ga.), where he conducted a college of music, which, however, did not prevent him from making several concert tours. His departure to Philadelphia (1890) called forth a public request to remain in Atlanta, which request, published in the *Constitution* (11 May 1890), was signed by the governor, the entire legislature of Georgia, the mayor of Atlanta and 150 of the prominent women of the State and city. Coming to Philadelphia he acquired full citizenship of the United States and founded the Sternberg School of Music, which has developed many pianists and composers who have gained national reputation. Withdrawing gradually from the concert stage he devoted his time to composition and has so far published over 300 pieces for the piano (many of which are in the concert programs of the present pianistic celebrities), a number of works for chamber music, which have had many public performances in Petrograd, Paris, Leipzig, Berlin and London, also several choral works and songs, amounting up to the present writing to 116 in opus numbers, many of these contain from 3 to 10 separate pieces. Sternberg is an accomplished linguist, the author of 'Ethics and Esthetics of Piano Playing' and a frequent contributor of essays to musical and other periodicals.

STERNBERG, stérn'berg, George Miller, American surgeon: b. Otsego County, N. Y., 8

June 1838; d. 1915. He was graduated from the College of Physicians and Surgeons, New York, 1860. He was appointed assistant surgeon in the United States army, 28 May 1861; captain and assistant surgeon, 28 May 1866; major and surgeon, 1 Dec. 1875; lieutenant-colonel and deputy surgeon-general, 12 Jan. 1891; and received the commission of brigadier-general, and surgeon-general in 1893. He was retired 8 June 1902. His first service during the Civil War was with the Army of the Potomac and later with the Army of the Gulf. After the war he was in charge of the United States General Hospital in Cleveland, Ohio, served through yellow fever and cholera epidemics, and during the war with Spain (1898), had command of the medical service. He was a member of the Havana Yellow Fever Commission, sent there by the National Board of Health (1879), and president of the American Medical Association (1898). He has published 'Photo-Micrographs, and How to Make Them' (1883); 'Bacteria, Malaria and Malarial Diseases' (1884); 'Manual of Bacteriology' (1893); 'Immunity, Protective Inoculations, and Serum-Therapy' (1897); 'Sanitary Lessons of the War' (1912). In 1885 he was awarded the Lomb prize of \$500 by the American Public Health Association for an essay entitled 'Disinfection and Individual Prophylaxis Against Infectious Diseases.'

STERNBURG, Herman von Speck, German diplomat: b. Leeds, England, 21 Aug. 1852; d. Heidelberg, Germany, 24 Aug. 1908. He was educated at the Fürstenschule Saint Afra, Meissen, Saxony, and the military academy of Potsdam, fought through the Franco-Prussian War in the Second Saxon dragoons, and remained in the military service until 1885. In 1890 he entered on his diplomatic career, being made successively first secretary of legation at Peking, charge d'affaires at Belgrade, Serbia, and first secretary of the embassy at Washington. In 1898 he was high commissioner on the Samoan commission; became consul-general for British India and Ceylon in 1900, minister plenipotentiary and envoy extraordinary to the United States in 1903, and ambassador in July 1903.

STERNE, stĕrn, Adolphus, Texan pioneer: b. Cologne, Germany, 5 April 1801; d. New Orleans, La., 27 March 1852. Leaving his birthplace in his 16th year to escape military duty, he came to the United States, going first to New Orleans and then visiting Texas in 1824. A lover of adventure and proficient in many languages and dialects, he joined the English settlers in their early struggles against the Mexicans, and took part in the Fredonian War. Saved from being sentenced to death by an amnesty, he went into business at Nacogdoches, and became a notable figure in eastern Texas. He studied law, was court interpreter, and after Texas won her independence he served in both upper and lower houses of Congress.

STERNE, Laurence, English humorist: b. Clonmel, Ireland, 24 Nov. 1713; d. London, 18 March 1768. He was a great-grandson of Richard Sterne, the master of Jesus College, who attended Laud to the scaffold and afterwards became archbishop of York. The archbishop's third son, named Simon, married Mary Jaques, heiress to the lordship of Elvington,

near York, on the river Derwent, and subsequently purchased Woodhouse Hall in the parish of Halifax. Their eldest son Richard succeeded to the two estates. Jaques, the third son, entered the church, and rose to many dignities, including an archdeaconry. Between them was born Roger Sterne, father of the humorist, who turned for a career to the army. When a mere stripling, Roger Sterne was appointed an ensign in the 34th regiment of foot and passed the rest of his life in service on the continent or in English and Irish barracks. He took part in the siege and capture of Vigo and in the defence of Gibraltar. In 1711 he married at Dunkirk, Agnes Hebert, of a humble Irish family and widow to a brother officer. Of their seven children only three lived beyond the fourth year. For 10 years the boy moved about with his parents from place to place, wherever the regiment happened to be stationed. Eventually the poor ensign left his family and went out to Jamaica, where he died of fever in 1731. As Laurence remembered him, Roger Sterne was "a little smart man . . . most patient of fatigue and disappointments . . . in temper somewhat rapid and hasty, but of a kindly, sweet disposition."

Long before this, Laurence had been placed, by the aid of his uncle Richard, in the Halifax grammar school, where he was kept at his accident for some seven years, and then sent to Cambridge on an allowance of £30 a year. Laurence Sterne was admitted to Jesus College as a sizar in 1733, and the next year he was elected to one of the several scholarships founded by his great grandfather. At the university the young man in no way distinguished himself, and in after life he ridiculed the curriculum. Graduating A.B., in January 1736-37, he was ordained deacon in the following March. In 1738 he was admitted to the priesthood and obtained, through the influence of his uncle Jaques, the vicarage of Sutton-in-the-Forest, eight miles from York. To this preferment was soon added the neighboring Stillington and a prebendal stall in York minster. On 30 March 1741 he married Elizabeth, daughter to Robert Lumley, sometime rector of Bedale, and immediately settled in the parsonage at Sutton. He lived there for 20 years. Two daughters were born, of whom only Lydia reached maturity. Besides officiating in his two parishes and taking his turns at preaching in the cathedral, the vicar cultivated his glebe and purchased two farms for large crops of oats and barley. He amused himself with fiddling and painting, read hundreds of books on all sorts of subjects and visited extensively among convivial squires. Possessing a facile pen, he wrote for a time political articles for his uncle Jaques, and twice he appeared in print with a sermon. A pamphlet called 'A Political Romance' (January 1795) brought to a gay close a hot dispute then waging in the York chapter. Aware now that he could write so as to make his reader laugh, he began 'The Life and Opinions, of Tristram Shandy, Gent,' the first two volumes of which were given to the public in December 1759. In the following March Sterne went up to London and met his great fame. After seeing through the press a second edition of his book and two volumes of sermons, he returned to the north and settled at Coxwold, a parish at the foot of the Hambleton Hills, which had

been bestowed upon him by Lord Fauconberg. In the parsonage there, renamed Shady Hall, Sterne went on with his comic romance, nine volumes in the whole, which appeared in further instalments near the beginning of several years down to 1767. Two more volumes of sermons were issued in 1765.

Never strong, Sterne broke down in January 1762, and hurried across the channel. After a brief stay in Paris, where statesmen, philosophers and the world of fashion crowded about him, he moved south to Toulouse, where he was joined by wife and daughter. He remained in southern France till the summer of 1764, when he returned alone to Coxwold. His health failing again, he set out for France in October 1765 on his famous sentimental journey. He traveled mostly by chaise from Calais via Montreuil to Paris, on to the south through Languedoc and then crossing over into Italy on to Rome and Naples. He was back at Coxwold in the summer of 1766. All this time his wife and daughter remained abroad. While in London for the winter of 1766-67, Sterne met and fell in love with Mrs. Elizabeth Draper, wife to a writer in the service of the East India Company. She sailed for India in April 1767 and poor Yorick was left broken-hearted. Mrs. Draper is the Eliza of the 'Sentimental Journey' and of a series of letters. After her departure for India, Sterne had a serious illness from which he barely recovered. In June he returned to Coxwold, where he recorded his sensations from day to day in a journal he kept for Eliza, and began 'A Sentimental Journey through France and Italy.' In the following January he went up to London with the new book, which was published on 26 Feb. 1768. He soon took to his bed and died 18 March 1768 at his lodgings in Old Bond street. At the time he was alone save for a nurse and a footman whom friends had sent to inquire after him. Four days later he was buried in Saint George's cemetery on the Bayswater road. According to a story which is probably true, his body was taken up and sold for dissection to the professors of anatomy at Cambridge. The next year Mrs. Sterne swept his study for three more volumes of sermons; and in 1775, Lydia, then Mrs. Medalle, brought out her father's letters and brief autobiography.

Sterne's career appeals strongly to the imagination. An obscure country parson till his 47th year, he at once became known throughout western Europe. Everybody wished to see the man who had written 'Tristram Shandy.' In London and in Paris there always awaited him "dinners a fortnight deep." A letter addressed to "Mr. Tristram Shandy, Europe," was handed him by the postboy on the way to Sutton. When Lessing heard of Yorick's death, he said that he would gladly have given him five years from his own life. See SENTIMENTAL JOURNEY, A; and TRISTRAM SHANDY.

Bibliography.—In 1780, Sterne's original publishers issued his work in 10 volumes. Of the numerous reprints, the best is the one edited by J. P. Brown (London 1873). It includes some additional letters. The convenient edition by Saintsbury (6 vols., London 1894) omits most of the sermons. The 'Works and Life' (12 vols., New York 1904), edited by Cross, contains the recently recovered 'Journal to Eliza,' additions to the correspondence, Mrs.

Draper's letters to friends in England, a body of anecdotes, and the 'Life' (annotated) by Fitzgerald. This standard biography by Fitzgerald, published in 1864, was revised in 1896 and reprinted in 1905. Consult also Traill's 'Laurence Sterne' in 'English Men of Letters Series' (London and New York 1882); Stapfer's 'Laurence Sterne, sa personne at ses ouvrages' (Paris 1870), and Thackeray's 'English Humorists.' Of more special interest are Texte's 'Rousseau et le cosmopolitisme littéraire au XVIII^{ème} siècle' (Paris 1895), and Thayer's 'Laurence Sterne in Germany,' with a bibliography (New York 1905).

WILBUR L. CROSS,
Professor of English, Yale University.

STERNE, Simon, American lawyer and economist: b. Philadelphia, 23 July 1839; d. New York, 22 Sept. 1901. He studied at the University of Heidelberg, was graduated from the law department of the University of Pennsylvania in 1859, and was admitted to the bar of New York in 1860. He represented many corporate interests, and paid special attention to real estate and constitutional law. He found time to take part in social and civic reform, lectured on political science at Cooper Institute (1861-63), and was secretary of the committee of 70 for the overthrow of the Tweed Ring (1870). He was appointed in 1875 on a commission to devise plans for the government of cities, and in 1895 on a commission to recommend changes in methods of administration; and by President Cleveland in 1896 to report as to the relations of western European governments to railways. Besides a large number of articles on historical and political economic subjects, he published 'Representative Government' (1871); 'Suffrage in Cities' (1878); 'Hindrances to Prosperity' (1879); 'Constitutional History and Political Development of the United States' (1882); 'Railways in the United States' (1912). Consult Foord, 'Life and Public Services of Simon Sterne' (1903).

STERNER, Albert Edward, American artist: b. London, England, 8 March 1863. He studied at Julien's Academy and the Ecole des Beaux Arts, Paris, and in 1881 came to the United States, opening his studio in New York in 1885. He is best known for his illustrations, which are effectively drawn and possess refinement and charm, while notable among his oil paintings are 'The Bachelor' and 'Portrait of My Son.' He became an associate of the National Academy of Design in 1910, and instructor at the Art Students' League and the New York School of Applied Design for Women.

STERNHOLD, stérn'hôld, Thomas, English hymnologist: b. Blakeney, Gloucestershire, about 1500; d. 1549. He was one of the versifiers of the first metrical version of the Psalms, long used in public worship in churches, but superseded by the version of Tate and Brady, published in 1698. He was educated at Oxford, became groom of the robes to Henry VIII, and held a similar office under Edward VI. The principal coadjutor of Sternhold in his versification of the Psalter was John Hopkins. The first edition (1548) contained 19 psalms, the second (1549) 37 psalms, translated by Sternhold, the third (1551) includes 7 trans-

lated by Hopkins. In 1562 appeared 'The Whole Book of Psalms.'

STERNUM, the breastbone in vertebrates. See ANATOMY, COMPARATIVE; ORNITHOLOGY; OSTEOLOGY.

STERRETT, James Macbride: b. Howard, Pa., 13 Jan. 1847. He graduated A.B., University of Rochester, 1867; A.M., Harvard University, 1870; B.D., Episcopal Theological School, Cambridge, Mass., 1872; D.D., University of Rochester, 1886. He was ordained in the Protestant Episcopal Church, 1872; served in Brooklyn, Wellsville, N. Y., and Bedford, Pa., 1872-1882; professor of ethics and apologetics in the Seabury Divinity School, Faribault, Minn., 1882-92; professor of philosophy in the George Washington University, 1892-1909; professor emeritus on The Carnegie Foundation, 1909; president, Society for Philosophical Inquiry, 1893-1910; rector of All Souls' (Sterrett) Memorial Church, 1911. He is author of 'Studies in Hegel's Philosophy of Religion' (1889); 'Reason and Authority in Religion' (1891); 'The Ethics of Hegel' (1893); 'The Freedom of Authority' (1905).

STERRETT, John Robert Sitlington, American educator and classical scholar: b. Rockbridge Baths, Va., 4 March 1851; d. 1914. He was educated at the universities of Virginia, Leipzig, Berlin, Athens and Munich. After holding professorships of Greek at Miami University and the University of Texas he was called to Amherst College, 1892-1901; he became head of Greek department at Cornell University, 1901. He was a professor in the American School of Classical Studies at Athens, Greece, 1896-97, led various archaeological expeditions to Asia Minor, and was a joint editor of the *American Journal of Archaeology*. Among his publications are 'Qua in re Hymni Homeric quinque majores inter se differunt' (1881); 'Inscriptions of Tralles' (1885); 'Notebook of a Traveling Archaeologist' (1889); 'The Torch-race' (1902); 'Research in Asia Minor and Syria' (1911).

STESICHORUS, stē-sīk'ō-rūs, Greek poet: b. Himera, Sicily, or perhaps Locrian Matarus, Italy, about 640 B.C.; d. Catana, 555 B.C. His own name, Tisias, he changed to Stesichorus ("conductor of the choric ode") as the inventor of strophe, anti-strophe and epode. With his predecessor, Alcman, he stands at the head of Dorian poets of the lyric dance. He incurred the wrath of Phalaris by the warning and poetic appeals which he addressed to his townsmen in view of the tyranny of that prince and died in exile. He employed folk-tales, the impersonal love poem and Epic-Doric dialect. He is considered one of the powerful influences in Greek poetry. He gave life and secular force to the Greek religious hymn, by giving it and his other poetry a more epic expression and form; and he is looked upon as the forerunner of Greek romance. He also set the style and versification for Greek lyric poetry so firmly that they suffered little subsequent change. His fragments are collected in Bergk's 'Poetæ Lyrici Græci.' Consult Farnell, G. S., 'Greek Lyric Poetry' (London 1891); Smyth, H., 'Greek Melic Poets' (London 1900); Wright, W. C.,

'A Short History of Greek Literature' (New York 1907).

STETEFELDITE, a mineral containing silver with copper, iron, antimony and sulphur. An ore of some importance in Klondike district, Nevada.

STETHOSCOPE, an instrument, the invention of Lænnec (q.v.), originally consisting of a short wooden tube, from 7 to 12 inches long, widening toward each end, with which physicians sounded the lungs by pressing on the chest or back and listening; also for diagnosing hernia, pregnancy, etc. The modern form of the instrument has two ear-tubes with flexible attachments, so that the physician hears simultaneously with both ears. The differential stethoscope permits comparison of sounds in different parts of the body. Another improvement is the phonendoscope, which renders audible more minute sounds.

STETSON, Francis Lynde, American jurist: b. Keeseville, N. Y., 23 April 1846. He was graduated at Williams College in 1867, took his LL.B. at Columbia University in 1869 and was admitted to the bar. He engaged in practice in New York and became known as an authority on corporation and railroad law. He was retained as general counsel by the United Steel Corporation, the International Mercantile Marine Company, the Northern Pacific and the Southern railroads, and the United States Rubber Company. He is also a railroad and corporation director. He is a trustee of Williams College and a director of the New York Botanical Gardens.

STETSON, John Batterson, American philanthropist: b. Orange, N. J., 5 May 1830; d. near Deland, Fla., 18 Feb. 1906. He engaged in hat manufacture and founded the John B. Stetson Company, with the largest factories in the world. Connected with them are reading-rooms, library, armory, etc. He built Stetson Hall for Deland University at Deland, Fla., and added other endowments, the name of the institution being changed to the John B. Stetson University.

STETTIN, stët-tën', Germany, in Prussia, capital and port of Pomerania, and of the government of Stettin, on the Oder, 60 miles north-east of Berlin. The old and new towns are distinct sections. Since the removal of the fortifications (1873) the town has extended greatly and several outlying villages have become incorporated in the main town. Both the Oder and the Parnitz, a tributary, are spanned by several bridges. There are numerous public squares embellished by statues of German sovereigns and other celebrities. There are many churches, of which the churches of Saint James (14th century) and Saint Peter's (1124) are most noteworthy, also a fine synagogue. Of secular buildings may be mentioned the royal palace (1346), now used for government purposes; the old town-hall, the exchange, asylum, orphan-home, concert-hall and club, arsenal, schools of architecture, technical school, etc. Stettin is one of Germany's chief ports and an important shipbuilding centre. The industries are varied and include iron-foundries, engineering works, manufacturing of ready-made clothing, chemical, cement, soap, oil, paper and

pasteboard works, sugar refineries and famous breweries and distilleries. In 1898 a free harbor east of the Lastadie suburb was opened, and in 1900 another new harbor on the east bank of the Oder. A ship-canal connects Stettin with Berlin, and ocean-going vessels now load and unload at its docks. The imports include coal, iron, soda and potash, seeds, coffee, cotton, wine, corn, herrings, timber; the exports are sugar, timber, liquor, grain, potatoes and flour. In the 12th century Stettin had already attained considerable importance. In 1121 Boleslas, Duke of Poland, introduced Christianity. The Treaty of Westphalia ceded the town to the Swedes, and it subsequently became a possession of Prussia. Pop. 257,400.

STEUART, stū'arī, John Alexander, Scottish novelist: b. Perthshire, 3 July 1861. After traveling extensively in North America he entered journalism, and returning to Europe settled in London and was editor of *The Publishers' Circular* (1896-1900). He has published 'A Millionaire's Daughters' (1888); 'Letters to Living Authors' (1890); 'The Eternal Quest' (1901); 'A Son of God' (1902); 'The Hebrews' (1903); 'The Red Reaper' (1905); 'Quicksands' (1907); 'Faces in the Mist' (1911); 'The Rock of the Ravens' (1912); 'Cupid, V. C.' (1916).

STEBEN, stū'bēn (Ger. stōi'bēn), Friedrich Wilhelm August Heinrich Ferdinand, BARON VON, Prussian soldier and American general: b. Magdburg, Prussia, 15 Nov. 1730; d. Steuben, Oneida County, N. Y., 28 Nov. 1794. Before coming to America he had attained the rank of lieutenant-general in the Prussian army, and had won distinction in the Seven Years' War. At its close he retired from military life, but was persuaded by colonial representatives in France to come to the assistance of the American people. He at once became an enthusiastic supporter of the American cause, and, tendering his services to Congress in 1777, was assigned to the main army under Washington at Valley Forge. His splendid discipline and ability as an organizer were at once recognized by Washington, who recommended his appointment as inspector-general of the entire army. Unable to attain a separate command in the open field, he spent most of his time recruiting the forces sent to those who took a more prominent part in the war; but it was undoubtedly due to his almost unrecognized efforts that the American troops were from the first so well organized and disciplined a body. He attained at last his coveted place as an officer in the line, and as major-general of the forces at Yorktown received the first offer of capitulation from Lord Cornwallis. Refusing to be relieved by Lafayette, he was allowed to remain with his command until the complete surrender of the enemy. At the close of the war he was refused pecuniary remuneration which he had asked of the colonies in the event of their success, but to recuperate his fortunes, abandoned for their cause, was subsequently awarded several grants of land, among them a township in northern New York, where he spent the remainder of his life in a log-cabin, within the present limits of Utica, N. Y., and where a monument to his memory was unveiled 3 Aug. 1914. Consult Sparks, 'American Biography'; Kapp, 'Life of Steuben' (1860).

STEBENVILLE, stū'bēn-vil, Ohio, city, county-seat of Jefferson County, on the Ohio River, and on the Pittsburgh, Chicago, Cincinnati and Saint Louis, the Cleveland and Philadelphia division of the Pennsylvania, the Wabash (Wheeling and Lake Erie) railroads, about 68 miles below Pittsburgh, Pa., and 23 miles north of Wheeling, W. Va. In 1786 a fort was built on the site of the present city. In 1798 the place was laid out as a town, and in 1851 it was incorporated as a city. It was one of the first American towns to use steam for manufacturing purposes.

The city is in an agricultural and coal and gas region, and has valuable clay deposits, petroleum wells and large quarries of excellent building stone. The chief manufacturing establishments are iron and steel, soap, tin plate and clay works, potteries, foundries, glass factories, blast furnaces, a paper mill, flour mills, boiler and tube works, machine-shops and nail and electric light furnishings and factories.

The city possesses numerous good churches, a high school opened in 1860 and public and parish schools, private commercial colleges, a Carnegie public and school libraries. It has four regular banks and two private banks and two building and loan associations. Pop. about 28,000.

STEUNENBURG, Frank, American statesman: b. Keokuk, Iowa, 8 Aug. 1862; d. December 1905. He removed to Caldwell, Idaho, in 1887 and engaged in the newspaper business. In 1889 he was a member of the convention which framed the State constitution, and in 1890 he was elected to the State legislature. He was elected governor of Idaho by the Populist party in 1898, and served in that capacity until 1901. He was assassinated by Harry Orchard (q.v.) in 1905, because of enmity engendered by his handling of the miners' strikes during his administration.

STEVENS, Abel, Methodist Episcopal clergyman and author: b. Philadelphia, Pa., 19 Jan. 1815; d. San José, Cal., 12 Sept. 1897. He studied at Wesleyan University, entered the New England Conference of the Methodist Episcopal Church in 1834, and held pastorates at Boston, Mass., and Providence, R. I. He was editor of *Zion's Herald* in 1840-52, of the *National Magazine* in 1853-54 and of the *Christian Advocate* in 1856-60. He returned to active duty as a pastor in New York and Mamaroneck, N. Y., in 1860-65, and in 1865-74 was joint editor of the *Methodist*. He subsequently traveled extensively in Europe, and was for a time in charge of the American Union Church at Geneva, Switzerland. His writings on the history of Methodism are exhaustive and authoritative. Author of 'Memorials of the Introduction of Methodism into the Eastern States' (2 vols., 1847-52); 'History of the Religious Movement of the Eighteenth Century, Called Methodism' (3 vols., 1858-61); 'The History of the Methodist Episcopal Church in the United States of America' (4 vols., 1864-77); 'A Compendious History of American Methodism' (1867); 'Madame de Stael' (2 vols., 1881); 'Christian Work' (1882), etc.

STEVENS, stē'vēnz, Alfred, Belgian painter: b. Brussels, 11 May 1828; d. Paris, France, 24 Aug. 1906. He studied under Navez

STATUE OF BARON VON STEUBEN

at Brussels and Roqueplan at Paris, and won a first-class medal at the Paris Exposition of 1867. He soon evinced striking talent in portraying fashionable and elegant life in Paris of the day—such as the lady in her boudoir, with all the bright, piquant accessories added in a spirit as suggestive, but not so bitter as that which characterized Hogarth, although his later pictures which take their subjects from common life had a distinctly ethical motif. Among his best-known canvases are 'The New Year's Gift'; 'Innocence'; 'The Allegory of Spring'; 'The Visit'; 'The Parisian Woman turned Japanese,' and 'Morning in the Country'. He also painted for the king of the Belgians four figures in fresco representing the four seasons,—female figures in modern costume. His 'Five O'Clock Tea' is in the Vanderbilt collection, New York.

STEVENS, Alfred George, English sculptor: b. Blandford, Dorsetshire, 1818; d. London, 1 May 1875. He was educated at the village school, and for a time followed his father's trade of house-painter. The assistance of a friend enabled him to study painting, architecture, and sculpture in Italy, where he lived from 1833 till 1842, being for some time a pupil of Thorwaldsen. After his return to England he became a teacher for two years in the School of Design. He is to be looked upon as one of the most important figures in the history of English sculpture. He was a follower of Michelangelo and the Renaissance, yet broke completely with the English tradition of stiff classicality, and worked naturally and freely at the dictates of his own individuality, bringing about something like a revolution in the ideals of English statuary. His influence was more active after his death, and during his lifetime his genuine strength and greatness were only known to the few. His great work is the monument to the Duke of Wellington in Saint Paul's. Consult Stannus, 'Alfred Stevens and His Work' (1891); Armstrong, 'Alfred Stevens: a Biographical Study' (1881).

STEVENS, Benjamin Franklin, American bibliographer, brother of Henry Stevens (q.v.): b. Barnet, Vt., 19 Feb. 1833; d. London, England, 5 March 1902. He studied at Middlebury College, and in 1860 went to London to engage with his brother Henry in his rare book business. He made a chronological catalogue of the American documents of the period 1763-84 in England, France, Holland and Spain, and likewise secured facsimiles of many important manuscripts concerning American history. For many years he was in charge of the Chiswick Press, and he was agent for many American libraries, as well as being United States dispatch agent in London. His publications include 'American Manuscripts in European Archives' (1887); 'The Campaign in Virginia in 1781' (2 vols., 1888); 'Facsimiles of Manuscripts in European Archives Relating to America, 1773-1783' (25 vols., 1889-98), etc.

STEVENS, Bertram, Australian author and critic: b. Inverell, New South Wales, 9 Oct. 1872. He entered journalism and became editor of a literary section called the 'Red Page' (in the *Sidney Bulletin*, 1909-11); and editor of the Australian magazine, *The Lone Hand* (1911-18). He has written and pub-

lished much on literary matters and has made two anthologies of Australian poetry, 'Anthology of Australian Verse' (1906) and 'Golden Treasury of Australian Verse' (1908). Among his other publications are 'Australian Birthday Book'; 'Bush Ballads'; 'The Charm of Sydney'; 'The Poetical Works of John Farrell, with Memoir'; 'Verses by Victor Daley, with Memoir.'

STEVENS, Ebenezer, American soldier: b. Boston, 1751; d. 1823. He was one of the Massachusetts colonists who took part in the memorable demonstration in Boston harbor in 1773, and was an active revolutionist from 1775 to the close of the war, during which he raised three Massachusetts companies for the siege of Quebec, and served as a commander in the battles of Ticonderoga, and later in the Virginia campaign. In 1778 he became lieutenant-colonel. He was also an officer in the War of 1812, engaged in the defense of the New York frontier. Later he was successful as a merchant in New York.

STEVENS, Edward, American soldier: b. Culpeper County, Va., 1745; d. there, 17 Aug. 1820. In 1776 he became colonel of the 10th Virginia regiment, the next year checked the forces of General Howe at the battle of the Brandywine, and after serving with distinction at Germantown, was appointed brigadier-general (1779). He served later at Camden, Guilford Court House, and at the siege of Yorktown, his gallantry being highly commended. After the adoption of the Virginia State constitution he was a member of the State senate till 1790.

STEVENS, Edwin Augustus, American inventor, capitalist and shipbuilder, son of John Stevens (q.v.): b. Hoboken, N. J., 1795; d. Paris, 7 Aug. 1868. He made numerous experiments in steam navigation and in 1861 urged the government to put into service his projected ironclad of 6,000 tons. This was not done and this first ironclad was never finished. The construction of this vessel was begun in 1854, under authorization by Congress; and \$1,000,000 left in Stevens' will to finish it was spent after his death in 1868. Finally the boat was sold for scrap iron in 1880. He inherited a large fortune from his father and his brother and endowed the Hoboken high school, and bequeathed \$1,000,000 to establish at Hoboken the Stevens Institute of Technology (q.v.). He was one of the foremost railroad organizers of the United States.

STEVENS, Edwin Augustus, American mechanical engineer, son and namesake of the founder of the Stevens Institute of Technology (q.v.): b. Philadelphia, 14 March 1858. He was graduated at Princeton in 1878 and has since resided at Hoboken, N. J., where he has been director and trustee in various corporations. He designed the first screw ferry-boat.

STEVENS, Frank Lincoln, American plant pathologist: b. Syracuse, N. Y., 1 April 1871. He was graduated at Hobart College in 1891, at Rutgers in 1893, later studied at the Ohio State University and took his Ph.D. at the University of Chicago in 1899; he also studied at the universities of Bonn and Halle, and at the Naples Zoological Laboratories. In 1902-12 he was professor of botany and plant

pathology at the North Carolina College of Agriculture and Mechanical Arts, also serving for a time as biologist of the North Carolina Agricultural Experiment Station. He was dean of the College of Agriculture and Mechanical Arts at the University of Porto Rico in 1912-14; and since 1914 has been professor of plant pathology at the University of Illinois. He was president of the American Phytopathological Society in 1910. Joint author of 'The Hill Readers' (1906); 'Diseases of Economic Plants' (1910); and author of 'The Fungi Which Cause Plant Disease' (1913), etc.

STEVENS, George Barker, American professor of theology: b. Spencer, N. Y., 13 July 1854; d. New Haven, Conn., 22 June 1906. He was graduated from the University of Rochester in 1887; held pastorates in a Congregational and Presbyterian church, 1880-85; studied in Germany, 1885-86; and became professor of New Testament criticism at Yale University in 1886. From 1895 till his death he was Dwight Professor of Systematic Theology in the Yale Divinity School. His publications include 'The Pauline Theology' (1892); 'The Johannine Theology' (1894); 'The Message of Paul' (1900); 'The Message of the Apostles' (1901); 'The Christian Doctrine of Salvation' (1905); 'The Theology of the New Testament' (1899); 'The Teaching of Jesus' (1909).

STEVENS, Henry, American bibliographer, brother of B. F. Stevens (q.v.): b. Barnet, Vt., 24 Aug. 1819; d. South Hampstead, England, 28 Feb. 1886. He studied at Middlebury College, at the Harvard Law School and was graduated at Yale University in 1841. He became interested in the bibliography of early American history and genealogy, and in 1845 went to London to execute a number of commissions for collectors of such works. He lived there the remainder of his life. He was agent of the British Museum to procure for it books and manuscripts produced in both North and South America, and through his efforts the Museum's collection of Americana was at the time the largest in the world. He collected for the Lenox Library, New York; and his collection of documents relating to Benjamin Franklin was purchased by the United States government. His bibliographical catalogues are of great value, being of rare accuracy and most minute in detail. He published many essays and pamphlets and edited many works on American history. He wrote 'Catalogue of a Library of Works Relating to America' (1854); 'Catalogue of the American Works in the Library of the British Museum' (1859); 'Bibliotheca Historica' (1870); 'Bibles in the Canton Exhibit' (1878); 'Historical Collections' (2 vols., 1881-86), etc.

STEVENS, Isaac Ingalls, American military officer: b. Andover, Mass., 18 March 1818; d. near Chantilly, Va., 1 Sept. 1862. He was graduated at the United States Military Academy in 1839, and served in the Mexican War as adjutant of engineers. From 1849 to 1853 he was in charge of the coast survey at Washington. In 1853 he resigned from the army to become governor of Washington Territory. At the outbreak of the Civil War he was made colonel of the 79th New York regiment. He was made a major-general 4 July 1862. He

was killed while leading a charge at Chantilly. He wrote 'Campaigns of the Rio Grande and Mexico' (1851).

STEVENS, John, American engineer and inventor: b. New York, 1749; d. Hoboken, N. J., 6 March 1838. He was graduated in law in 1771. In 1787, having accidentally seen the imperfect steamboat of John Fitch, he at once became interested in steam propulsion, and experimented constantly for the next 30 years on the subject. In 1789 he petitioned the legislature of New York for a grant of the exclusive navigation of the waters of that State. The petition was accompanied with drafts of the plan of his steamboat, but the right was not granted because the boat did not meet the exactions made by Congress. The following year he again petitioned Congress, this time for laws to protect American inventors. Out of this petition and subsequent active interest in the matter on the part of Stevens have sprung the present American patent system. In 1804 he constructed a propeller, a small open boat worked by steam, and his success was such that he built the Phenix which ran for six years on the Delaware river, a steamboat, which was completed but a very short time after Fulton had finished the Clermont. Fulton having obtained the exclusive right to the navigation of the Hudson, Mr. Stevens placed his boats on the Delaware and Connecticut. In 1812 he published a remarkable pamphlet urging the government to make experiments in railways traversed by steam carriages. The first steam ferry in the world was established by him in October 1811, connecting Hoboken with New York. His locomotive model (1826) was exhibited in operation and it has been claimed as the first locomotive run on a track in this country. His other inventions and improvements were many and various.

STEVENS, John Austin, American banker, son of Ebenezer Stevens (q.v.): b. New York, 22 Jan. 1795; d. there, 19 Oct. 1874. He was graduated at Yale University in 1813, and became his father's partner in the mercantile business in 1818. He was president of the New York Bank of Commerce in 1839-66. As chairman of a committee of bankers of New York, Boston and Philadelphia he greatly assisted the United States government in negotiating its loans during the Civil War, and he was frequently called into consultation by the Treasury Department. He was for many years secretary of the New York Chamber of Commerce and was one of the organizers of the New York Merchants' Exchange, of which he was the first president.

STEVENS, John Austin, American author: b. New York, 21 Jan. 1827; d. 16 June 1910. He was graduated at Harvard in 1848, when he entered commercial life, becoming secretary of the New York Chamber of Commerce (1862-68), and later, librarian of the New York Historical Society. He was founder of the Society of the Sons of the Revolution and the Loyal League, and was the founder and for many years editor of *The Magazine of American History* (1877-83). He wrote 'The Expedition of Lafayette against Arnold'; 'The Burgoyne Campaign'; 'Progress of New York in a Century'; 'The French in Rhode Island' and 'Life of Albert Gallatin,' 'The Valley of

the Rio Grande'; 'Colonial Records of the New York Chamber of Commerce'; 'New York City.'

STEVENS, John F., American civil engineer and railroad official; b. Gardiner, Me., 25 April 1853. He was assistant engineer of the city of Minneapolis in 1874-76, and was afterward engaged in railroad engineering. In 1889 he became connected with the Great Northern Railroad and in 1902-03 he was its general manager. He was later connected with the Rock Island Railroad, and in 1904-05 he was second vice-president of the Pacific Railroad. He was appointed chief engineer of the Panama Canal in 1905, at the time when its construction policy was being determined, and for two months before he resigned, 1 April 1907, he was also chairman of the Isthmian Canal Commission. He was vice-president of the New York, New Haven and Hartford Railroad in 1907-09; and in 1909-11 he was president of the Spokane, Portland and Seattle, the Oregon Trunk and other western railroads.

STEVENS, John Leavitt, American writer and diplomat; b. Mount Vernon, Maine, 1 Aug. 1820; d. Augusta, Me., 8 Feb. 1895. He was ordained in 1844 in the Universalist ministry, but was obliged to give up the profession, in 1854, on account of ill-health. He became associated with James G. Blaine on *The Kennebec Journal* in 1855; went to the Maine legislature, 1865-68, and to the State senate, 1868-70. He was minister from the United States to Uruguay and Paraguay, 1870-73; and to Norway and Sweden, 1877-83. In 1889 he was sent as minister to the Hawaiian Islands, and in 1890 his rank was raised to that of Envoy Extraordinary and Minister Plenipotentiary. In 1893, having placed the islands, then in revolution, under the protection of the United States, Stevens was recalled by President Cleveland, who did not approve of his course; but he was exonerated by the Senate. He is the author of 'The History of Gustavus Adolphus' (1884) and a collaborator on 'Picturesque Hawaii' (1894).

STEVENS, Lillian M. N., American temperance worker; b. Dover, Me., 1 March 1844; d. Portland, Me., 6 April 1914. She was married to Michael Stevens of Portland, Me., in 1867. In 1874 she was one of the organizers of the Maine Women's Christian Temperance Union, was its treasurer in 1874-77 and its president the remainder of her life. She was also vice-president of the National Women's Christian Temperance Union in 1894-98 and its president from 1898 until her death. She was one of the lady managers of the Columbian Exposition in 1892-93.

STEVENS, Phineas, American soldier; b. Sudbury, Mass., 20 Feb. 1707; d. Chignecto, N. S., 6 Feb. 1756. At 16 he was carried captive by the Indians from Rutland, Mass., to Saint Francis, Canada and learned their mode of warfare. During King George's War he commanded Fort No. 4, now Charlestown, N. H., and he held this post successfully against the French and Indians till the close of the war. He was sent to Canada in 1749 to negotiate for exchange of prisoners and again in 1752. For journal of his trip in 1749 consult 'New Hampshire Historical Collections.' His travels

in the American Colonies was edited by D. N. Mereness (New York 1916).

STEVENS, Robert Livingston, American inventor; b. Hoboken, N. J., 18 Oct. 1787; d. there, 20 April 1856. He was a son of John Stevens, inventor. He early became interested in steam navigation and made many improvements in the construction of vessels, among which was that of giving concave water lines to the hull. In 1813 he invented the beam-engine, percussion shells for smooth-bore guns, and in 1836 introduced the T-rail on the Camden and Amboy Railroad, of which he was president. He made many improvements in the marine engine.

STEVENS, Thaddeus, American statesman; b. Danville, Vt., 4 April 1792; d. Washington, D. C., 11 Aug. 1868. He was graduated at Dartmouth College in 1814; went to York, Pa., where he taught school. He was graduated in law, and began to practise in Gettysburg. In 1828 he joined the Whig party, and became active in politics. He worked with the party of anti-Masonry (q.v.), and took part in its Baltimore convention (September 1831). In 1833 and for several succeeding years he was a member of the Pennsylvania legislature, acted with the Whigs, and became distinguished through his opposition to slavery. At the State constitutional convention in 1836, to which he was a delegate, he advocated negro suffrage. During his legislative career he was engaged in fighting the party "machine," and in the end came off victorious. He was appointed a canal commissioner in 1838, and rendered important services to the State in developing its system of internal improvements. Removing to Lancaster, Pa., in 1842, he there engaged for six years in the practise of law. In 1848 and again in 1850 he was elected to Congress, where he strongly opposed the fugitive-slave law (see FUGITIVE-SLAVE LAWS), the Kansas-Nebraska Bill (q.v.), and other measures involving concessions to Southern interests. Again in 1858 he was elected to Congress, and became the acknowledged leader of the House, in which he remained as such until his death. Throughout the Civil War he was chairman of the Committee on Ways and Means, and afterward held the chairmanship of the Committee on Reconstruction. He reported from that committee the Reconstruction Act of 1867, having previously (1865) assisted in framing the Wade-Davis Reconstruction Bill. (See UNITED STATES). He was also chairman of the House committee which had charge of the impeachment of Andrew Johnson (q.v.). Stevens was a man of boundless energy and tenacity of will, with the intenseness of a zealot in the cause which he espoused; and in respect to slavery his radicalism outran that of all its other congressional opponents. Consult Callender, E. B., 'Thaddeus Stevens' (Boston 1882); McCall, 'Thaddeus Stevens' (in 'American Statesmen Series,' 1899); Woodburn, 'Thaddeus Stevens' (Indianapolis 1913).

STEVENS, Walter B., American journalist; b. Meriden, Conn., 25 July, 1848. Graduated University of Michigan, A.B., 1870; A.M., 1872; honorary degree of LL.D., from Washington University, Saint Louis, in 1908. From 1870 he was connected with Saint Louis newspapers; was Washington correspond-

ent of the Saint Louis *Globe-Democrat*, 1884-1901; president of the Gridiron Club, 1895. As staff correspondent he traveled in Canada, Cuba, Mexico, Porto Rico, Jamaica, Panama and the United States writing in serial form letters over the signature "W.B.S." on *The New States*, *Convict Camps*, *In a Silver Country*, *Black Labor in the South*, *Signs of the Times*, etc. He was secretary, director of exploitation and member of the superior jury, World's Fair of 1904; secretary of the National Prosperity Association in 1908; secretary of the Saint Louis Centennial Association in 1909; executive secretary of the Fourth American Peace Congress in 1913, secretary of the Saint Louis City Plan Commission, 1912-16. He has written 'Through Texas,' 'The Ozark Uplift,' 'The Forest City,' 'A Trip to Panama,' 'Notes on Facsimiles of Robert Burns,' 'The Building of Saint Louis,' 'Saint Louis The Fourth City,' 'The Log of the Alton,' 'The Brown-Reynolds Duel,' 'Water Purification at Saint Louis,' 'Life of Samuel Morris Dodd,' 'Book of the Fourth American Peace Congress, Saint Louis,' 'Nights With Burns,' 'Eleven Roads to Success,' 'Missouri the Centre State,' 'Halsey Cooley Ives,' 'Lincoln and Missouri,' 'Grant in Saint Louis.'

STEVENS, Walter Le Conte, American physicist: b. Gordon County, Ga., 17 June 1847. He was graduated at the University of South Carolina in 1868, and later studied at the universities of Strassburg, Berlin and Zürich. He was appointed professor of mathematics and physics at Packer Institute in 1882; was professor of physics at Rensselaer Polytechnic Institute in 1892-98; and since 1898 has been professor of physics at Washington and Lee University. He has specialized in physiological optics and acoustics, and is author of numerous scientific papers. He revised Steele's 'Physics' (1888).

STEVENS, William Arnold, American philologist and Baptist theologian: b. Granville, Ohio, 5 Feb. 1893; d. 2 Jan. 1910. He was graduated at Denison University in 1862 and later studied at the Rochester Theological Seminary and at the universities of Harvard, Leipzig and Berlin. He was professor of New Testament interpretation at the Rochester Theological Seminary in 1877-1910. Author of 'Select Orations by Lysias' (1876); 'Commentary on the Epistles to the Thessalonians' (1887); 'A Harmony of the Gospels for Historical Study' (1894; 3d ed., 1904); and joint author of 'Outline Handbook of the Life of Christ' (1892); 'Life of the Apostle Paul' (1894), etc.

STEVENS INSTITUTE OF TECHNOLOGY, is located at Castle Point, Hoboken, N. J. It was founded in 1870 by Edwin A. Stevens, who bequeathed about two acres of land, \$150,000 for buildings, and \$500,000 for an endowment for "an institution of learning." The trustees decided that the new "institution" should be a college of mechanical engineering and in 1871 it was opened to students, being the first college course in America devoted to mechanical engineering and the first to give the degree of "Mechanical Engineer." The founder, himself an engineer of achievement, was the son of John Stevens and the brother of Robert L. Stevens both famous in the early

annals of American engineering. The Institute offers but one course of study for all students, requiring four years and leading to the degree of M.E. It has bestowed the honorary degrees of Doctor of Philosophy, Doctor of Science and Doctor of Engineering on prominent scientists and engineers. The subjects taught are basic in both science and economics and are designed to produce successful men in electrical, civil, chemical, hydraulic and other branches of practical engineering, as well as in mechanical engineering. In addition to the lecture and classroom subjects in science and business principles, the Institute maintains a foundry, blacksmith shop, machine shop, carpenter shop, drafting rooms, physical, chemical, electrical and experimental engineering laboratories in all of which there are organized courses which every student must pursue. During the entire four years the student is under the supervision of a physical director and is required to report twice a week for individual and class exercise. Henry Morton, Ph.D., LL.D., Sc.D., was the first president, being succeeded at his death in 1902 by Alexander C. Humphreys, M.E., Sc.D., LL.D. The Institute is governed by a board of 20 trustees, eleven of whom are Stevens graduates. Three of these serve as representatives of the Alumni Association for temporary periods of three years each. The principal increases in grounds, buildings and endowment have been: a total of \$145,000 from Henry Morton for current uses, 1871-1902; grounds and buildings from Mrs. E. A. Stevens valued at \$30,000, 1897; a laboratory of engineering and an endowment amounting to \$350,000 from Andrew Carnegie, 1899-1911; land valued at \$15,000 from Robert L. Stevens, 1905; \$90,000 in the form of contributions from the Alumni toward the Morton Laboratory of Chemistry which was dedicated in 1906; a total of \$26,000 from Dr. Edward Weston for extension of plant; \$80,000 secured by President Humphreys from friends of the college, toward purchase of Castle Point property, 1910-1913; \$1,385,000 from an intensive campaign for subscriptions in 1915, of which Andrew Carnegie gave \$250,000, the Rockefeller Foundation, \$250,000; William Hall Walker, \$100,000, the remainder coming from alumni and friends. With these and other gifts the entire plant now includes about 23 acres situated on elevated ground on the bank of the Hudson River immediately overlooking New York City and harbor. It includes five large buildings used for instruction purposes, one of these being a large and well-equipped gymnasium constructed in 1916, from the subscription of William Hall Walker given expressly for this purpose. Stevens Castle, for several generations the home of the Stevens family, was secured in 1911 and is now used as a dormitory and social centre. The endowment funds in 1917 amounted to \$1,625,000 and the entire plant was valued at about \$2,800,000. The Institute offers 28 free scholarships of which 10 are available each year. Four of the scholarships are open to all, their presentation being in the control of the president of the college; the remainder are in the gift of specially designated schools, or of organizations that have provided funds for the endowment of scholarships. There is a special loan fund for students who need financial assistance. Six

prizes, ranging from twenty dollars to fifty dollars, are offered each year for proficiency in chemistry, physics, general scholarship and accomplishment in student activity as measured by the upbuilding of character and its influence on student life.

STEVENS POINT, Wis., city, county-seat of Portage County; on the Wisconsin River, and on the Wisconsin Central and the Green Bay, Wisconsin and Saint Paul railroads; about 20 miles northeast of Grand Rapids and 100 miles north of Madison. It is the commercial and industrial section of the southern part of a rich pine district and has extensive lumbering interests. The river furnishes good water-power. The chief manufacturing establishments are several lumber mills, planing mills, foundries, flour mills, railroad shops, machine shops, furniture factories and important productions of self-rocking cradles and artificial flies for anglers. The educational institutions are private commercial schools, a high school, public and parish schools, a State normal school, a Polish convent and a public library. Two national banks have a combined capital of \$150,000 and one State bank has a capital of \$60,000. Pop. \$12,000.

STEVENSON, stē-vēn-sōn, **Adlai Ewing**, American statesman: b. Christian County, Ky., 23 Oct. 1835; d. 1914. He was educated at Centre College, Danville, Ky., but without graduating removed to Bloomington, Ill., in 1852. He was admitted to the bar in 1857 and was master in chancery from 1860 to 1864. He took an active part in politics as a Democrat, and in 1875-77 and 1879-81 represented Illinois in the National House of Representatives. In 1885 was appointed first assistant postmaster-general but he antagonized the advocates of civil service reform by his wholesale removal, on political lines, of employees of the post office department; and after the renomination of Grover Cleveland in 1892 was chosen the candidate for the vice-presidency. The Democratic candidates were elected, and after the expiration of his term he was appointed by President McKinley a member of the American commission to visit Europe and endeavor to secure the adoption of international bimetalism. In 1908 he was Democratic candidate for the governorship of Illinois.

STEVENSON, **Andrew**, American statesman: b. Virginia, 1784; d. Blenheim, Va., 25 June 1857. He studied law, attained a prominent position at the bar, in 1804 was elected to the house of delegates of Virginia, and after being a member for several sessions was chosen Speaker. In 1821 he was elected a representative in Congress and for 13 years held that office, for the last six of which he was Speaker of the House. He was minister to England from 1836 to 1841, and on his return became rector of the University of Virginia.

STEVENSON, **Burton Egbert**, American novelist, dramatist and anthologist: b. Chillicothe, Ohio, 9 Nov. 1872. He was educated at Princeton University, and entered newspaper work in 1893. Since 1899 he has been librarian of the Chillicothe Public Library. His novels are 'At Odds with the Regent' (1900); 'A Soldier of Virginia' (1901); 'The Heritage' (1902); 'Tommy Remington's Battle' (1902);

'The Holladay Case' (1903); 'Cadets of Gascony' (1904); 'The Marathon Mystery' (1904); 'The Young Section Hand' (1905); 'The Girl with the Blue Sailor' (1906); 'The Young Train Dispatcher' (1907); 'That Affair at Elizabeth' (1907); 'The Quest for the Rose of Sharon' (1909); 'The Young Train-master' (1909); 'The Path of Honor' (1910); 'The Mystery of the Boule Cabinet' (1912); 'The Gloved Hand' (1913); 'The Destroyed' (1913); 'Little Comrade' (1915). Mr. Stevenson's travels have resulted in two books, 'The Spell of Holland' (1911), and 'The Charm of Ireland' (1914). He is the editor of Theodore Winthrop's posthumous novel, 'Mr. Waddy's Return,' and of the Condensed Classics edition of Fielding's 'Tom Jones.' He is the editor and compiler of 'Days and Deeds—Verse' (1906); 'Days and Deeds—Prose' (1907); 'Poems of American History' (1908); and the author of 'A Child's Guide to Biography' (1909). He is also the compiler of the anthology 'The Home Book of Verse' (1912) and of the companion 'Home Book of Verse for Young Folks' (1915). He has done editorial work for various publications; is a contributor to the leading magazines; and the author of the play, 'Little Comrade,' a dramatization of his novel of the same name.

STEVENSON, **Edward Luther**, American cartographer and historian: b. Rozetta, Ill., 18 Oct. 1860. He was graduated at Franklin College, Indiana, in 1881, and afterward studied at the universities of Johns Hopkins, Jena, Halle and Heidelberg, taking his Ph.D. at Heidelberg in 1890. He was professor of history at Rutgers College in 1891-1911, and in 1910-15 he was secretary of the Hispanic Society of America. Since 1917 he has been lecturer on historical geography at the University of California. He is a leading authority on cartography, and in 1913 was made a Knight of the Royal Order of Isabelle the Catholic of Spain. Author of 'Maps Illustrating the Early Exploration and Discovery of America, 1502-1530' (1902-06); 'The Marine World Chart of Nicolo de Canerio Januensis' (1908); 'Early Spanish Cartography of the New World' (1909); 'Willem Janszoon Blaeu, 1571-1638' (1914); 'Terrestrial and Celestial Globes' (1917), etc.

STEVENSON, **John James**, geologist: b. New York, 10 Oct. 1841. He was graduated at New York University in 1863 and was professor of geology in his alma mater, 1871-1909 and since professor emeritus. He was United States geologist, 1873-74, 1878-80; was the geologist of the Pennsylvania geological survey, 1875-78, 1881-82; and was president of the New York Academy of Sciences, 1896-98. He published several geological treasures, among which are 'Geology of a Portion of Colorado' (1875); 'Report on Greene and Washington Districts, Pa.' (1876); 'Geology of Bedford and Fulton Counties, Pa.' (1882); 'Monograph on Carboniferous of the Appalachian Basin' (1903-07); 'Formation of Coal Beds' (1911-13), etc.

STEVENSON, **Joseph**, Scottish historian: b. Berwick-upon-Tweed, 27 Nov. 1806; d. London, 8 Feb. 1895. He studied at the University of Glasgow, and in 1831 was appointed to a position in the manuscript department of the British Museum, where in 1834 he became a

sub-commissioner of the permanent records. He was reared in the Presbyterian Church, but in 1839 he was ordained in the Anglican Church. He was one of the editors of the *Rolls Series* of historical works under the title 'Chronicles and Memorials of Great Britain and Ireland' which the British government undertook at his suggestion in 1847. In 1863 he again changed his faith, entering the Roman Catholic Church, in which he was ordained priest in 1872. He was commissioned by the government to make a detailed examination of the Vatican archives, a work occupying four years and resulting in 13 volumes of transcripts now in the keeping of the Public Records Department. He edited numerous works for learned societies, as well as for the collections of the 'Church Historians of England,' and he was joint editor of 'Scottish National Memorials' (1890).

STEVENSON, Joseph Ross, American Presbyterian clergyman and educator: b. Ligonier, Pa., 1 March 1866. He was graduated at Washington and Jefferson College in 1886, at the McCormick Theological Seminary in 1889, later studied at the University of Berlin and was ordained in 1890. He was engaged as a pastor until 1894, when he became connected with the faculty of the McCormick Theological Seminary, where in 1897-1902 he occupied the chair of ecclesiastical history. He was in charge of the Fifth Avenue Presbyterian Church in 1902-09, and of Brown Memorial Church, Baltimore, in 1909-14. Since 1914 he has been president of the Princeton Theological Seminary. He was elected moderator of the Presbyterian General Assembly in 1915.

STEVENSON, Matilda Coxe, American ethnologist: b. San Augustine, Tex., 1855; d. 24 June 1915. Her maiden name was Evans and she was married to James Stevenson, an ethnologist, in 1872. From him she received instruction in ethnology, and for 13 years she was engaged with him in ethnological exploration in the Rocky Mountains. Left a widow in 1888 she was appointed to the staff of the Bureau of American Ethnology of the Smithsonian Institution, and was thereafter especially engaged in study of the Pueblo tribes of New Mexico and the Taos and Tewa Indians. Author of 'Zuñi and the Zuñians' (1881); 'Religious Life of the Zuñi Child' (1887); 'Zuñi Ancestral Gods and Masks' (1898); 'The Zuñi Indians; their Mythology, Esoteric Fraternities and Ceremonies' (1903), etc.

STEVENSON, Robert, Scottish engineer: b. Glasgow, 8 June 1772; d. Edinburgh, 12 July 1850. Having studied engineering, he was appointed engineer and superintendent of Scottish lighthouses. In 1843 he had constructed 23 lighthouses on the coast of Scotland. He was the originator of the intermittent or flash light now in general use. The famous Bell Rock Lighthouse, described in the Diary of Sir Walter Scott, was built by Stevenson in 1807-10 after overcoming tremendous difficulties. He was the grandfather of Robert Louis Stevenson.

STEVENSON, Robert Louis (baptized Robert Lewis Balfour), Scottish novelist, essayist, and poet: b. 8 Howard place, Edinburgh, 13 Nov. 1850; d. Vailima, island of Upolu,

Samoa, 3 Dec. 1894. He was the only child of Thomas Stevenson, an eminent light-house engineer,—as his father, Robert Stevenson, had been before him,—and Margaret Isabella, daughter of the Rev. Lewis Balfour, of Colinton in Midlothian. He was a playful, imaginative child; was fond of being read to, and commenced to compose (by dictation) at the age of six. His health was infirm from the first; but he was tended and kept alive by a devoted nurse, Alison Cunningham, to whom he remained affectionately grateful throughout his life. His schooling was irregular and inconsecutive; and even while attending school he showed a truant disposition. On his many rambles, he always took a copy-book, in which he tried to fit into words his impressions of people and places, imitating the cadences of his favorite authors. In 1867 he entered Edinburgh University, and studied engineering with a view to following the family profession. He showed, however, little interest in this; though in 1871 he won a silver medal for a paper on light-house apparatus. The same year he gave up engineering, and began to study law. He was called to the bar in 1875; but immediately forsook the legal profession also, and turned his attention entirely to letters.

Acute nerve exhaustion and danger to the lungs forced him to spend the winter of 1873 at Mentone. In 1874 he joined the Savile Club in London, and soon made friends with many of the most prominent literary men of the day, including Sidney Colvin, William Ernest Henley, Edmund Gosse, Andrew Lang, Walter Pollock, Leslie Stephen, Cosmo Monkhouse, Sir Walter Simpson, George Meredith and Prof. Fleeming Jenkin. His social charm was irresistible, and he was noted for the brilliancy and ardor of his talk. Henley's sonnet, 'Apparition,' gives a vivid description of him at this period. He practised writing constantly. In April 1875, he made his first visit to the artist haunts of Fontainebleau, in company with his painter cousin, R. A. M. Stevenson. In 1876, in company with Simpson, he took the canoe trip from Antwerp to Grez, which he afterward narrated in his first book, 'An Inland Voyage' (1878); and in 1878 he went alone upon the tramping trip which resulted in 'Travels with a Donkey' (1879). These little books of travel stamped him already as a master of English prose style, though they were written with more elaborate mannerism than he showed in his maturer work. Meanwhile, beginning 1876, he contributed to the *Cornhill* and other magazines the critical essays later collected in 'Familiar Studies of Men and Books' (1882), and the bracing and vigorous papers on life and the living of it, collected in 'Virginibus Puerisque' (1881). As a critic he showed thorough study and sympathetic insight, and as a moralist he displayed a militant gaiety and bracing bravery of spirit. His first published stories were 'A Lodging for the Night' (1877); 'The Sire de Malétroit's Door' (1878), and 'Will o' the Mill' (1878). His first volume of fiction was 'New Arabian Nights,' which appeared serially June to October 1878. These early stories showed at once his romantic love for the poetry of circumstance, and his mastery of rapid and brilliant narrative.

Soon after the inland voyage of 1876, Stevenson met in France an American lady, Mrs. Fanny Van de Grift Osbourne, for whom he conceived almost immediately a devotion that changed the entire course of his life. Her domestic circumstances had been unhappy, and on her return home in 1878, she took steps to obtain a divorce from her husband. Learning her determination, Stevenson resolved to follow her, and started suddenly for California in August 1879. He undertook the journey against the remonstrances of his family and friends. He was very short of funds; and therefore crossed the ocean in the steerage, and traversed the continent in an emigrant train. The experiences of this double journey he afterward narrated in 'The Amateur Emigrant' and 'Across the Plains.' On board ship he wrote 'The Story of a Lie,' under stress of immediate need for money. The hardships that he genially endured resulted in a general breakdown of his health. From September to December 1879, he lived at Monterey and worked incessantly. In December 1879, he moved to San Francisco, where for three months he lived in a workman's lodging, and was reduced almost to the point of death by enforced frugality and excessive labor. Mrs. Osbourne nursed him back to life. She was now free from her former husband, and Stevenson married her in May 1880. Immediately afterward, in order to insure his recovery, the couple moved to a deserted mining camp in the California Coast Range. An account of their experiences here is given in the 'Silverado Squatters.'

In August 1880, Stevenson brought his wife to England, where she was enthusiastically welcomed by his parents and friends. During the next two years he spent his summers in Scotland and his winters, on account of his precarious health, at Davos Platz, in Switzerland, where he enjoyed the companionship of John Addington Symonds. At Davos he completed 'Treasure Island,' a stirring narrative for boys, both young and old, that made his fame as an artist in romance. It appeared serially in *Young Folks* from October 1881 to January 1882, and was published in book form in 1883. The author received £100 for the book rights of the story, and was delighted at the price, little knowing how the work was destined to endure. From 1882 to 1884 he lived in the south of France, partly at Marseilles and Nice, but chiefly at Hyères. In 1884 he returned to England and settled at Bournemouth, where he remained till 1887. His health was at its lowest ebb during this period. A great part of his time was spent necessarily in bed; often, because of his tendency to hemorrhages, he was forbidden to speak aloud. In spite of this handicap, he kept cheerfully at work, and produced, besides many minor stories of the highest merit, the graceful and urbane romance, 'Prince Otto' (1885), the thrilling and adventurous 'Kidnapped' (1886), and 'The Strange Case of Dr. Jekyll and Mr. Hyde' (1886), that terrible and searching tale of the good and bad in man. In 1885 he also published 'A Child's Garden of Verses,' a collection of poems showing such unsophisticated memory and intimate understanding of childhood as to make its author the poet laureate of the nursery. During the same period he

composed four plays in collaboration with W. E. Henley; but his attempts in the dramatic form were never of great importance. In 1887 appeared 'The Merry Men and Other Tales,' a volume which collected some of his most artistic novelettes and short stories, among them being 'Markheim,' a grim tale of conscience and remorse; and also 'Memories and Portraits,' a collection of papers chiefly autobiographical.

The death of Stevenson's father in May 1887, severed the strongest tie which bound him to the old country; and weary of battling for health in an unpropitious climate, he accepted the advice of his physicians to try a complete change of surroundings. Accordingly, with his wife and mother, he sailed to America in August 1887. He spent the next winter at Saranac Lake, in the Adirondack Mountains. His main work that season was the preparation of 12 articles for *Scribner's Magazine*, which appeared one a month through 1888, and the composition of a large part of 'The Master of Ballantrae,' perhaps his most attractive romance. Among the *Scribner* papers were several of his greatest essays on literature and life,—for example, 'The Lantern Bearers,' 'Pulvis et Umbra' and 'A Christmas Sermon.' In June 1888, he crossed the continent to San Francisco; and being subsidised by large advance orders for travel letters and other literary work, sailed forth with his entire family on the schooner yacht *Casco* for a long voyage to the South Sea Islands. His first extensive stay was at Honolulu, 1889, where he completed 'The Master of Ballantrae' and also 'The Wrong Box,'—the latter in collaboration with his step-son, Mr. Lloyd Osbourne. Thence, in the schooner *Equator*, he proceeded to Samoa and Sydney. From Sydney, after voyaging to many islands on the steamer *Janet Nicoll*, he returned to Samoa, bought an estate named Vailima on a mountain slope above Apia in the island of Upolu, and determined to settle there for good. From 1891 to his death he lived at Vailima, building a great house and dwelling with a feudal dignity emulous of Scott's at Abbotsford. He was beloved by all the natives,—who called him "Tusitala," teller of tales,—took an active interest in Samoan affairs, and became, by the force of his engaging personality, a real power in the land. At Vailima he produced 'The Wrecker' and 'The Ebb Tide,' both in collaboration with Mr. Osbourne; a sequel to 'Kidnapped,' called 'Catriona, or David Balfour'; a collection of 'Island Nights Entertainments'; sundry writings about Samoan affairs; and three-quarters of a romance called 'St. Ives,' completed after his death by Mr. A. T. Quiller-Couch. In all of this work he was aided by his step-daughter, Mrs. Isobel Strong, who proved to be a devoted amanuensis. He also commenced 'Weir of Hermiston,' which gave promise of being by far the greatest of his novels. He labored on this book with feverish intensity until the very day of his death. The end came suddenly. With characteristic gaiety of spirit, he was making a salad on the veranda, when a blood-vessel burst in his brain. He lost consciousness immediately, and died within two hours. The Samoans bore his body to the summit of Vaea

Mountain, where he lies buried. See *TREASURE ISLAND*; *KIDNAPPED*; *DR. JEKYLL AND MR. HYDE*.

Bibliography.—All the material really necessary for a study of Stevenson is comprised in the Edinburgh and Thistle Editions, including the 'Life,' by Graham Balfour, and the 'Letters,' edited by Sidney Colvin (4 vols., New York 1911). Consult also the biography by Graham Balfour (2 vols., New York 1901); Simpson, E. B., 'Stevenson Originals' (New York 1912); Mrs. R. L. Stevenson, 'The Cruise of the Janet Nicoll among the South Sea Islands' (ib. 1914); Pinero, A. W., 'Robert Louis Stevenson as a Dramatist' (ib. 1914); James, Henry, in 'Notes on Novelists' (ib. 1914); and Hamilton, Clayton, 'On the Trail of Stevenson' (Garden City, N. Y., 1915); Rice, R. A., 'Stevenson, How to Know Him' (New York 1916).

CLAYTON HAMILTON,
Sometime Tutor in English, Columbia University.

STEVENSON, Sara Yorke, American archaeologist: b. Paris, France, 19 Feb. 1847. She was educated in Paris, lived in Mexico, and came to America in 1862, where in 1870 she was married to Cornelius Stevenson. She received the degree of Sc.D. from the University of Pennsylvania, the first degree ever conferred on a woman by that institution. In 1897 she went to Rome on a special mission for the departments of archaeology and palæontology of the University of Pennsylvania, and in 1898 was sent to Egypt for the American Exploration Society, to make investigation in connection with archaeological work in the Nile Valley. She was vice-president of the jury, for ethnology, Chicago Exposition, 1893; and has been assistant curator of the Pennsylvania Museum since 1908. She has been various times president of the Civic Club of Philadelphia and was the first woman lecturer on the Harvard Calendar (1894). Since 1908 she has been literary editor of the *Public Ledger* of Philadelphia. She has published 'Maximilian in Mexico' and 'The Book of the Dead.'

STEWART, Sir William Jukes, Australian statesman and author: b. Reading, England, 1841; d. 2 Nov. 1912. He went to New Zealand in 1862 and a few years later entered journalism and became successively editor of the *North Otago Times*, *Wainmate Times* and the *Ashburton Mail and Guardian*. Elected to the house of Representatives in 1870 he held his seat until his death and during this long tenure of office had many important commissions and offices in connection with the legislative body, among that of speaker (1891-93). He was knighted in 1902. Among his published works are 'Carmina Varia' (1867); 'The Vision of Aorangi and Other Poems' (1906); 'Parliamentary Procedure in New Zealand' (1906). A great deal of his most interesting work is in the files of magazines and newspapers.

STEWART (Anglo-Saxon, *stig*, cattle-pen, and *weard*, guard) in common usage, a head servant who attends to domestic matters in a house, club, hotel or other establishment. (1) On shipboard an officer whose duty it is to distribute provisions to the officers and men. In passenger ships, a man who superintends

the distribution of provisions and liquors, waits at table, etc. (2) A fiscal agent of certain bodies; as, the recording steward of a congregation of Methodists. (3) The Lord High Steward of England was one of the ancient officers of state, the greatest under the crown. A lord high steward is now made only for particular occasions, such as a coronation or the trial of a peer. (4) The Steward of the Household, an officer of the English royal household, who is head of the court called the Board of Green Cloth, which has the supervision of the household expenses and accounts. He selects the officers and servants of the household and he appoints the royal tradesmen. This office is of very ancient origin and was hereditary, though not always in the same line, until 1319, when Henry IV merged it with the crown.

STEWART, stū'art, Alexander P., American military officer: b. Rogersville, Tenn., 2 Oct. 1821; d. Biloxi, Miss., 30 Aug. 1908. He was graduated from the Military Academy in 1842 and after serving in the artillery for three years resigned from the army. When the Civil War came Stewart was appointed a major of artillery by Governor Harris of Tennessee. His promotion was rapid. He was made a major-general on 2 June 1863 and lieutenant-general on 23 June 1864, almost a year before the close of the war. In 1868 he accepted the chair of professor of mathematics in the University of Mississippi, and from 1874 to 1886 was chancellor.

STEWART, Alexander Turney, American merchant: b. Belfast, Ireland, 12 Oct. 1803; d. 10 April 1876. He came to the United States in 1823 and engaged in teaching. In 1825 he founded in New York, a dry-goods business which gradually expanded into one of the largest mercantile concerns in the world. He was at one time considered the wealthiest man in the United States and was a giver of large sums of money to various charitable institutions, and was active in many philanthropic undertakings. Before his death the business of which he was head had branches and agencies in the principal cities of Europe and several factories and mills at home. He was buried in Saint Mark's churchyard, from which his remains were stolen on 7 Nov. 1878. They were afterward recovered and deposited in the mausoleum of the Cathedral of the Incarnation, erected by Mrs. Stewart in memory of her husband at Garden City, Long Island.

STEWART, Alvan, American lawyer and reformer: b. South Granville, Washington County, N. Y., 1 Sept. 1790; d. New York, 1 May 1849. He moved with his parents to Vermont, where in 1809 he entered Burlington College. He spent some time in Canada in 1811-12, but in the latter year returned to college. During the War of 1812 he again went to Canada and was held as a prisoner. On his return to the United States he studied law and began the practice of his profession at Cherry Valley, N. Y., where he rapidly attained success. In 1832 he moved to Utica and continued his practice, but gave a large share of his time and attention to the temperance and anti-slavery causes. His first anti-slavery speech was delivered in 1835; in 1837 he called and organized

an anti-slavery convention at Utica, which was, however, soon dispersed by mob violence. He was the leader in New York State in forming an independent political party to promote the abolition of slavery, and was that party's candidate for governor. Among his most famous speeches are those delivered before the New Jersey Supreme Court to establish the unconstitutionality of slavery in the State under the Constitution of 1844, and one delivered in 1837 to prove that Congress could constitutionally abolish slavery. His speeches were edited by L. R. Marsh and published under the title, 'Writings and Speeches of A. Stewart on Slavery.'

STEWART, Balfour, Scottish physicist: b. Edinburgh, 1 Nov. 1828; d. near Drogheda, 18 Dec. 1887. He was educated at Dundee and later at the University of Edinburgh. In 1859 he was appointed director of the observatory at Kew and in 1870 professor of physics, Owens College, Manchester. He is best known by his investigations into the absorption and radiation of heat and his remarkable meteorological studies, especially those undertaken in collaboration with De la Rue and Loewy on the physical constitution of the sun, and with Tait on the generation of heat in a vacuum. He devoted most of his labors to the study of terrestrial magnetism. His main discovery on the subject of heat constituted a remarkable extension of what is known as Prévost's "Law of Exchanges," and he established the fact that radiation is not a surface phenomenon, but takes place throughout the interior of the radiating body, and that the radiative and absorptive powers of a body must be equal. He published 'Elementary Treatise on Heat' (1866); 'Elementary Physics' (1870); 'Physics' (1872); 'The Conservation of Energy' (1872); 'Practical Physics' (1885); 'Terrestrial Magnetism,' in the 'Encyclopedia Britannica' (9th ed., etc.). Consult 'Men and Women of the Time' (12 ed.).

STEWART, Bertrand, English army captain: d. August 1914 in action, reported to be the first man killed in the British expeditionary force in France. Though a lawyer by profession, he had held a commission in a Yeomanry regiment for many years, had served through the South African war as a trooper and was attached to the staff of Sir John French at the time of his death. Stewart was arrested in Bremen, Germany, on 7 Aug. 1911 on a charge of espionage. He was accused of visiting various towns and islands (where he had never been) and of attempting to secure secrets concerning German military and naval defences and the North Sea dockyards. He was made the subject of a bitter press campaign in Germany and described as "the gentleman spy," ferretting out secrets to the advantage of "our adversary," as England was openly designated. He was tried in camera and on the evidence of only one witness was sentenced to three and a half years' imprisonment in a fortress 3 Feb. 1912. He was released in May 1913 as an act of clemency on King George's visit to Berlin.

STEWART, Charles, American naval officer: b. Philadelphia, Pa., 28 July 1778; d. Bordentown, N. J., 7 Nov. 1869. Shipping on a merchant ship at the age of 13, he eventually became captain. In 1798 he entered the navy

as a lieutenant on board the frigate *United States* and served on this vessel among the West Indies and against French privateers. In 1800 he returned to the marine service and was captain of several schooners. Later he commanded privateers. In this latter capacity he captured the French vessels *Deux Amis* and *Diane*. In 1804 he joined the Mediterranean squadron, where he took command of the *Siren* in operations against Tripoli. On his return to the United States in 1806 he was promoted to the rank of captain. In 1813 he commanded the *Constitution* in a cruise to the Guiana coast and the Windward Islands, which resulted in the capture of the British schooner *Piston* and a number of merchant vessels. In 1815 he made a second cruise in the same vessel and captured two large British ships, the *Cyane* and the *Levant*, but he was later defeated by the British and lost the *Levant* to them. In 1816-20 he commanded a squadron in the Mediterranean and from 1821-23 he had command of a Pacific squadron. He was also in command of the home squadron (1842-43). In 1857 he was placed on the retired list, but two years later took charge of the Philadelphia Navy Yard, which office he held for three years, when he was retired as rear-admiral.

STEWART, Dugald, Scottish philosopher: b. Edinburgh, 22 Nov. 1753; d. there, 11 June 1828. He was the son of Matthew Stewart, who for 25 years was professor of mathematics at Edinburgh University, and there young Dugald studied from 1765 to 1769, devoting himself to mathematics and philosophy. In the latter subject his teacher was Adam Ferguson. In 1771 Stewart went to Glasgow, partly to prepare himself as a candidate for one of the Snell scholarships at Oxford, and partly to attend the lectures of Thomas Reid, who came to exercise a profound influence on the young student. In 1772 he was called upon by his father, whose health was failing, to teach the mathematical classes in the University of Edinburgh. In 1775 he was elected joint professor and acted in that capacity till 1785. During Ferguson's absence on a political mission in America in 1778-79, Stewart also had charge of the courses in philosophy, and upon the resignation of Ferguson in 1785 was chosen to succeed him and continued in the active duties of his class for 25 years. His field embraced a wide array of subjects: psychology, logic, metaphysics, ethics, natural theology, the principles of taste, politics, and last of all, political economy. In 1792 appeared the first volume of the 'Elements of the Human Mind,' followed in 1793 by the 'Outlines of Moral Philosophy.' In the same year he read before the Royal Society of Edinburgh his 'Account of the Life and Writings of Adam Smith'; in 1796 came the 'Account of the Life and Writings of Principal Robertson,' and in 1802 the 'Account of the Life and Writings of Dr. Reid.' In 1806 he received a sinecure office worth £300 a year. The death of his second son in 1809 proved a severe blow for his health, otherwise indifferent, and he was unable to conduct his lectures during the following session. Thomas Brown was appointed as conjoint professor, and Stewart passed the rest of his life in retirement. In 1810 he published his 'Philosophical Essays'; in 1814 the second volume of the 'Elements of

the Human Mind'; in 1815 the first part and in 1821 the second part of 'A Dissertation on the Progress of Metaphysical, Ethical and Political Philosophy since the Revival of Learning'; in 1827 the third volume of the 'Elements'; and in 1828, a few weeks before his death, the 'Philosophy of the Active and Moral Powers.' Stewart has little claim to be considered an original thinker, and his chief importance rests in the success which attended his attempt to expound the philosophy of Thomas Reid. From the latter he differed chiefly in his more sympathetic attitude toward the Cartesian philosophy, and in certain principles of psychology, notably those connected with the subject of association. A gifted orator and possessed of an extremely attractive personality, Stewart attained very great popularity as a lecturer and he was successful in implanting in the minds of his hearers a profound respect for the value of philosophic thought and the standards of a lofty morality. His works, in 11 volumes, appeared in 1854-58 and included the 'Life,' by John Veitch. Consult also McCosh, 'Scottish Philosophy' (1875); Stephen, 'English Thought in the 18th Century.'

STEWART, George, Canadian journalist: b. New York, 26 Nov. 1848; d. 1906. He early removed with his parents to the province of New Brunswick, Canada, and was educated there. He edited and published *Stewart's Literary Quarterly Magazine* in 1867-72, and was afterward engaged in newspaper work, serving as editor of the Quebec *Daily Chronicle* in 1879-96. Author of 'Canada Under the Administration of the Earl of Dufferin' (1878); 'Emerson the Thinker' (1879); 'Essays from Reviews' (1892-93), etc.

STEWART, George Black, American Presbyterian clergyman and educator: b. Columbus, Ohio, 28 Feb. 1854. He was graduated at Princeton University in 1876, later studied at the McCormick Theological Seminary and was graduated at the Auburn Seminary in 1879. He was ordained in 1879 and held pastorates until 1899, when he became president of Auburn Seminary. He also holds the chair of practical theology there. He was founder of the Pennsylvania Chautauqua, of which he was president for five years. He is a contributor to religious periodicals, is editor of the Auburn Seminary *Record*, and is author of 'Life of Jesus for Juniors' (1896); 'A Study of the Life of Jesus' (1907); 'Efficiency Tests for Pastors and Churches' (1915), etc.

STEWART, James, Canadian physician and educator: b. Osgoode, Ontario, 1846; d. 1906. He was graduated in medicine at McGill University in 1869 and afterward engaged in practice as a physician. He was professor of materia medica and therapeutics at McGill University in 1883-91, held the chair of clinical medicine there in 1891-93 and from 1893 was also professor of medicine. He was president of the Association of American Physicians in 1903. He wrote extensively on neurology, and was for many years one of the editors of the *Montreal Medical Journal*.

STEWART, Julius, American artist: b. Philadelphia, Pa., 6 Sept. 1855. He studied under Gérôme and Madrazo at Paris, and lived there the greater share of his life. He is

known as a figure and genre painter. His style is decidedly French in finish, but his characterizations of American types is excellent, particularly his studies of the American colony in Paris. He was a member of the executive and advisory committee of the Saint Louis Exposition in 1904. He was awarded gold medals at Berlin in 1891 and 1895 and at Munich in 1897 and 1901. He was elected a chevalier of the Legion of Honor in 1901. His 'Hunt Ball' is in the Essex Club, Newark, N. J.

STEWART, Matthew, Scottish mathematician: b. Rothesay, 1717; d. Edinburgh, 23 Jan. 1785. He studied at the University of Glasgow, and in 1746 published his 'General Theorems of Considerable Use in the Higher Parts of Mathematics.' In 1761 he published 'Tracts Physical and Mathematical,' and in 1763 'Propositiones Geometricæ More Veterum Demonstratæ.'

STEWART, Robert, marquis of Londonderry. See CASTLEREAGH.

STEWART, William Rhinelander, American humanitarian: b. New York, 3 Dec. 1852. He was graduated at the Columbia Law School in 1873, and engaged in law practice, but abandoned it in favor of his work as executor and trustee and for philanthropic work. He became in 1908 the president of the Rhinelander Real Estate Company. He was commissioner on the New York State Board of Charities from 1882, was its president in 1894-1900 and has occupied that office since 1904. He was president of the 25th National Conference of Charities and Correction in 1898; in 1900 he organized the New York Board of Charities and Correction, serving as its president in 1903, and in 1910 he organized a similar conference for New York City. In 1889 he organized the committee that erected Washington Arch in Washington square, New York, and served as its treasurer. He was one of the committee of 70 organized in 1894 for the purpose of defeating Tammany Hall. Author of 'The Philanthropic Work of Josephine Shaw Lowell' (1911).

STEWART ISLAND, New Zealand, the smallest and southernmost of the three main islands composing New Zealand (q.v.). It is separated by Foveaux Strait from the southern extremity of South Island. Its area, together with the neighboring islets, is 665 square miles, and its population about 300.

STEWARTIA, a genus of the tea family, which contains ornamental shrubs and trees, found only in eastern America and eastern Asia. They have simple, membranous, deciduous leaves, which turn to brilliant autumnal coloring, and solitary, axillary flowers. These blossoms are large and showy, cup-shaped and like camellias. They have usually five petals and numerous stamens; the fruits are capsules, somewhat woody and contain lenticular seeds, sometimes winged. The two American white-flowered species, from the Southern States are *S. malachodendron*, bearing the largest flowers of the genus, and *S. pentagyna*, flowering in late spring and summer. These are sometimes cultivated, but *S. pseudo-camellia* is more widely known. In its original habitat, mountainous Japan, this species is a tall tree, with smooth, bright-red bark, flaking off in thin, large pieces. It has handsome, elliptical, dark-green leaves,

not troubled by insects, and creamy-petaled flowers, with wavy edges, purple filaments and orange stamens. Like the *S. pentagyna*, it is hardy as far north as Massachusetts.

STEYER, stî'ër, or **STEYR**, stir, a city in Austria, at the junction of the Steyer with the Enns, 19 miles southeast of Linz. The town proper has two suburbs connected by bridges, and there are three public squares, one of which contains beautiful fountains. The buildings are typically Italian: the parish church is modeled on Saint Stephen's of Vienna; the town-hall is embellished by a graceful tower; the Castle of Lemberg (10th century) stands upon a rocky height overlooking the rivers. There are several monuments, a grammar school, technical and industrial schools and museum. Steyer is one of the most important manufacturing cities of Austria and very wealthy. The factories for iron and steel, paper, calico, woollens, leather, cutlery, hosiery, bell-founding, dyeing, small-arms, and bicycles are among the most important of the country. The historical interest of the town centres in the treaty of peace concluded there 25 Dec. 1800 between Austria and France. Pop. 18,000.

STEYN, *Marthinus Theunis*, ex-president of the Orange Free State, South Africa: b. 2 Oct. 1857; d. 28 Nov. 1916. Of Dutch (Boer) descent, his mother was a daughter of Wessels, one of the leaders of the Great Trek in 1836. He studied law in England, was called to the bar and returned to South Africa to practise in Bloemfontein. He became a judge before he was 40, and was elected President of the Orange Free State in 1895. In the South African War of 1899 he threw in his lot with President Kruger. Both republics were annexed by Great Britain as a result of the war and were federated under the Union of South Africa in 1910. Though he subscribed to the Constitution, Steyn was strongly suspected of favoring the rebellion of 1915. See BEYERS; ORANGE FREE STATE, PROVINCE OF THE; WAR, EUROPEAN.

STIBICONITE, a mineral consisting of hydrous-oxide of antimony, $\text{Sb}_2\text{O}_3 \cdot \text{H}_2\text{O}$. It contains 74.05 per cent of antimony and is an important ore in Nevada and California.

STIBNITE, ANTIMONITE, or ANTIMONY-GLANCE, the only important ore of antimony. It crystallizes in the orthorhombic system and forms not only in acicular crystals often radially grouped, but also, in Japan, in magnificent groups of large crystals, prismatic and deeply striated vertically, which are undoubtedly among the finest of mineral specimens. The crystals are often twisted, while angular bends, due to gliding planes, are very common. Massive, granular and columnar forms also occur. Brachypinacoidal cleavage is highly perfect. Though flexible, even when in large, stout crystals, and slightly sectile, it seems very brittle because of its easy cleavage. It is very soft, hardness 2; specific gravity 4.6; lustre metallic, splendid; color and streak lead-gray, becoming black and often iridescent on exposure to light. Chemically it is antimony trisulphide, Sb_2S_3 . It fuses even in large pieces in the flame of a candle and is number one in the scale of fusibility. It occurs in many localities throughout central Europe, in England,

China, Mexico, New Brunswick, and in the United States in Arkansas, Utah, California and elsewhere. See also ANTIMONY.

STICK-INSECTS. See WALKING-STICK.

STICKIT MINISTER, The, and Some Common Men, a collection of short stories by Samuel Rutherford Crockett (q.v.), published in 1893.

STICKLEBACK, a small fish of the family *Gasterosteidae*, order *Hemibranchii*, in which the rays of the first dorsal fin form a series of detached spines. The body is elongated and compressed and tapers behind to a narrow caudal peduncle. Teeth exist in both jaws, but are absent from the tongue and palate. The premaxillary is protractile. The sides of the body may be covered with vertical bony plates, while the other parts are destitute of any scaly covering. These fishes inhabit the rivers and brackish waters of temperate climates of the northern hemisphere. The brook stickleback (*G. bispinosus*), very common on the New England and New Jersey coasts and sometimes in fresh water, is a voracious little fish, swimming eagerly after bait of all kinds, and not at all disturbed by noises and acts which would infallibly frighten away most other fishes. It is highly pugnacious, especially at the breeding season. In its reproductive habits it evinces many most interesting features, constructing a nest and attending its young with care and affection. The nest is the size of a large hickory-nut and is composed of vegetable matters, pieces of straw, sticks and the like, bound together with a silky fibre secreted by an organ closely connected with the kidneys of the male. In the top of the nest a small pit is formed in which the eggs are deposited. These are about the size of poppy seeds, and are bright-yellow. Over this nest and its contained ova the fishes watch with the most jealous care, the male taking upon himself almost the entire duty of nidification, as well as of tending the young after hatching. The genera *Eucalia*, *Pygosteus* and *Apeltes* are all represented in the salt or fresh waters of the United States, where are found seven species of these interesting little fishes, each exhibiting individual peculiarities in appearance and habits. Consult Gill, 'Standard Natural History,' Vol. III (Boston 1885), and Ryder, 'Bulletin United States Fish Commission' (Washington 1881).

STIEGLITZ, *Julius Oscar*, American chemist: b. Hoboken, N. J., 26 May 1867. He was graduated at the Realgymnasium, Karlsruhe, Germany, in 1886; took his Ph.D. at the University of Berlin in 1889; and after his return to the United States studied at Clark University. He was connected with the faculty at the University of Chicago from 1892, became professor of analytical chemistry there in 1905, director of the laboratories in 1912, and since 1915 has been chairman of the chemical department. He was Hitchcock lecturer at the University of California in 1909, and became a member of the National Academy of Sciences in 1911. Author of papers on molecular rearrangements, carbamid bases, imido ethers and related subjects and of 'The Elements of Qualitative Chemical Analysis' (2 vols., 1911-12).

STIGAND, stig'and, William, English clergyman: b. 1002; d. 1064. He enjoyed great favor with King Edward, who in 1044 made him royal chaplain and bishop of Elmham or of the East Angles. Eight years later the bishop mediated successfully in the interests of peace between the king and Earl Godwin, and was awarded with the archbishopric of Canterbury. Stigand received the pallium from Pope Benedict X. On the death of Harold, Stigand gave his vote for Edgar Atheling to be king, and for this reason, and because he was a firm friend of the House of Godwin, William the Conqueror distrusted him, and induced the Pope to send a commission of cardinals, who deprived him of his dignities and sentenced him to perpetual imprisonment. But Stigand died shortly afterward in Winchester, starved to death, it is said.

STIGMA, plural, stigmas, or stigmata (Greek *stigma*, mark, puncture, brand), a mark made with a red-hot iron; a brand impressed on slaves and others. The original Greek signification of the word has received many secondary meanings. Owing to its association with the branding of slaves, stigma has come to have the signification of a mark of infamy, a slur attached to any one on account of evil conduct. In anatomy stigma bears a meaning closer to the original signification of the word which was to puncture with a sharp pointed instrument. This sense is closely related to that of the English verb "to stick," meaning to pierce, puncture or stab (with a pen or other pointed weapon). The expression "to stick one with a stick" conveys the meaning and shows the derivation of the English word, which is related to the English to sting, and the German *stechen*, to prick, pierce, sting thrust and stab. These being the equivalents of stigma in the English language, the Greek word came to have, in English, a more or less popular usage, only one of its significations, and that metaphorical, being derived from its association with slaves and outcasts, the official marks on whom came to be symbolical with social and moral degradation.

But science has gone back to the original sense of the Greek word and has given us numerous scientific terms in modern English, derived from the Greek or from its Latin derivative. In anatomy and zoology stigma is used in the sense of a mark, point or noticeable place, as for example a naevus, a birth-mark. The place on the surface of an ovary where there is a rupture of a mature Graafian follicle is termed a stigma. The word also signifies a chitinous mark on the anterior margin of the forewings of numerous insects. It is the term used to designate the interior orifice of a trachea, a spot of pigment in protozoa, one of the pores of the segmental organs; a ciliated opening connecting the cavity of the pharynx with that of the artificial canal. Any mark on the skin which bleeds periodically or even at irregular intervals is also termed a stigma. None of these uses of the term departs from the root meaning of the word, which, as we have seen, was to puncture or prick, with the substantive sense of the thing punctured or pricked.

In botany the stigma is a part of the style, or in the absence of the latter, of the surface of the ovary, which receives the pollen.

Stigma was used in Greek grammar as a signature which is still used sometimes for "st." It also designated the number six.

STIGMATA, the Greek plural form of stigma, is used in various collective significations. Anatomical stigmata, for instance, comprises irregularities or malformations of various parts of the anatomy, among them being those of the face, the skull-cap, palate, teeth, tongue, lips, nose, ears, limbs, fingers, thorax and, in general, any part of the human anatomy. The presence of less or more than four fingers on one human hand would be stigma, as would be the dwarfing or over growth of the frame of man or animal. Abnormal conditions of the skin, hair and limbs are also characterized as stigmata. Often these persistent stigmata are used as signs by which to judge abnormal conditions or physical, mental or moral degeneracy in an individual. These abnormalities have been classified by Peterson as belonging to (1) motor functions; (2) sensory functions; (3) speech; (4) genitro-urinary function; (5) instinct or appetite; (6) diminished resistance to diseases and external influences; (7) delayed development of puberty.

Under the head of psychical stigmata are classified all kinds of irregular functions of the mind from simple feeble-mindedness, eccentricity, moral delinquency and sexual perversion to idiocy and imbecility. In this section stigmata have been divided and subdivided by scientists and specialists into a large number of classes and a vast number of interesting and important experiments have been made to show the relation of each separate abnormality to the normal individual. Frederick Peterson, an authority on the subject of deformities, for example, found only 10 per cent of abnormal palates among persons apparently otherwise normal and 40 per cent among feeble-minded persons. Another investigator found 35 per cent of abnormal palates among people subjected to general paralysis; 70 per cent among hysterical insane; 76 per cent in epileptics; 80 per cent among hopelessly insane; and 82 per cent among idiots. But apparently the investigations did not show whether the diseases were affected by the abnormalities or the latter the direct or indirect result of the diseases. See EUGENICS; HEREDITY; PSYCHOLOGY OF THE ABNORMAL.

Y., July 1896); Petrus de Alva y Astorga, 'Prodigium naturæ portentium gratiæ' (Strassburg 1664); Raymond, 'Opera' (Vol. 13, Lyons 1665); Schmieder (in Evan-

gelische Kirchenzeitung' (pp. 183, 345, Berlin 1875); Steill, 'Ephemerides dominicano sacræ' (Dillingen 1692); Thiepolus, 'De passione Christi'; Thorluck, 'Vermischte Schriften' (Hamburg 1839).

STIGMATIZATION, derived from the Greek word *stigma*, a puncture, the name applied by Roman Catholic writers to the impression on certain individuals of the "stigmata," or marks of the wounds which Christ suffered during the course of His Passion. In the early days many Christians branded the name of Christ on their foreheads, and various voluntary mutilations for Christ's sake were practised by enthusiasts. The stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion, but also those impressed by the crown of thorns and by the scourging. The most remarkable example of stigmatization is that narrated of Saint Francis of Assisi and occurring in 1224, on the mountain of Alverno. Being absorbed in rapturous contemplation of the Passion of Christ, he saw a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified, descend from heaven and approach him, so as to be almost in contact. After a time the vision disappeared, leaving the soul of Francis filled with reverence and awe. And now he became aware that in hands, feet and side he had received externally the marks of crucifixion. These mysterious marks continued during the two years until his death, and are declared by the saint's biographers to have been seen by many eye-witnesses, including Pope Alexander IV.

The Dominicans openly disputed the fact, but at length made the same claim for Catharine of Sienna, whose stigmata were explained as at her own request made invisible to others. The Franciscans appealed to Sixtus IV, and that pope, himself a Franciscan, forbade representations of Saint Catherine to be made with the stigmata. Still the fact is recorded in the breviary office, and Benedict XIII granted the Dominicans a special feast in commemoration of it. Many others, especially women, are enumerated as having received all or some of the stigmata. Among these is Saint Veronica Giuliani, who is said to have received in 1694 first the marks of the crown of thorns, and afterward those of the crucifixion. More recent cases are those of Anna Katherina Emerich (1774-1824), who became a nun at Agnetenberg; 'L'Ecstatica' Maria von Morl of Caldaro (1839); Louis Lateau (1850-83, in 1868), whose stigmata were stated to bleed every Friday; and Mrs. Girling (1827-86, about Christmas 1864), of the New Forest Shaker community. Dr. Imbert-Gourbeyre, in his work 'Les Stigmatisées' (1873), enumerates 145 persons, of whom but 20 were men, as having received the stigmata, and of these 80 lived before the 17th century. By 1894 he had collected 321 examples of stigmatization. Apart altogether from the question of the value of the evidence offered, we may reasonably conclude that some kind of stigmatization is a pathological condition of occasional occurrence. The Roman Catholic Church is extremely cautious in giving credence to cases of stigmatization as genuinely supernatural and Theodor Schwann, a professed Catholic professor at Louvain and

a noted biologist, who carefully looked into the subject, refused to admit for stigmatization other than a perfectly natural character. See **STIGMATA**.

STIKINE, stik-ën', **STAKHIN**, a Tlingit tribe of the Koluschan linguistic stock of North American Indians, about the mouth of Stikine River, southern coast of Alaska. They are divided into the Wolf and the Raven clans. In 1880 they numbered 317 in eight villages, but by 1890 they had diminished to 255.

STILBENE DYE STUFFS. See **COAL-TAR COLORS**.

STILBITE, one of the commonest of the zeolite family of minerals. Though crystallizing in the monoclinic system, its crystals simulate rhombic forms on account of their twinning which is uniformly present and which is revealed by polarized light under the microscope by the division into sectors whose extinction angles are 10°. These twin crystals are often grouped into the curious sheaf-like bundles so characteristic of the species. Clinopinacoidal cleavage is perfect; fracture uneven; brittle; hardness 3.5 to 4; specific gravity 2.2; lustre vitreous, pearly on the clinopinacoid; color usually white or yellowish, though not infrequently brownish to brick-red; transparent or translucent. Essentially a hydrous silicate of aluminum and calcium, generally with a little soda. Before the blowpipe it acts like scolecite (q.v.). It mostly occurs in cavities in trap rocks. Many localities have yielded fine specimens, among the most important being Poona, India; Iceland; Farøe Islands; Nova Scotia; Paterson and Upper Montclair in New Jersey. Sphæro-stilbite and pufferite are globular varieties.

STILES, stilz, **Charles Wardell**, American zoologist: b. Spring Valley, N. Y., 15 May 1867. He was educated at Wesleyan University, Conn., 1885-86; Collège de France, 1886-87; Berlin University, 1887-89; Leipzig University, 1889-90; Trieste Zoological station, 1891; Pasteur Institute and Collège de France, 1891. He was zoologist, 1891-1902, and has been consulting zoologist since 1902, in the bureau of animal industry, United States Department of Agriculture. He has been professor of zoology in the United States Public Health Service since August 1902; professor of medical zoology at Georgetown University 1892-06; at Johns Hopkins University since 1897; and United States Navy Medical School since 1902; and was a special lecturer on that subject at the Army Medical School, 1894-1902; scientific secretary of Rockefeller Sanitary Commission, 1909-14. He has held other offices as consultant with national and private scientific institutions, has represented the United States government at several International Zoological Congresses, and was detailed as agricultural and scientific attaché to the United States Embassy, Berlin, 1898-99; secretary of International Commission on zoological nomenclature since 1896. His publications, chiefly on medical zoology and sanitation include 'A Revision of the Adult Cestodes of Cattle, Sheep and Allied Animals' (1893); 'Tapeworms of Poultry' (1896); 'Internal Parasites of the Fur Seal' (1899); 'The Cattle Ticks of the United States' (1902); 'Report on Hook Worm Disease in the United States' (1903); 'Index-Catalog of Medical and

Veterinary Zoology, 7 vols., etc. Outside of scientific circles he is known chiefly because of his medical studies among the tenant whites of the South, upon the medical side of the negro problem and child labor, and because of his connection with the hookworm problem.

STILES, Ezra, American clergyman and college president: b. North Haven, Conn., 15 Dec. 1725; d. New Haven, Conn., 12 May 1795. He was graduated from Yale in 1746, and was a tutor there 1749-55. Dr. Franklin having sent an electrical apparatus to Yale, Stiles entered with great zeal upon this then new field of philosophical investigation, and performed the first electrical experiments ever made in New England. At the time he was pursuing the study of theology, was licensed, and commenced his ecclesiastical work in June 1749. In April 1750 he visited the Housatonic tribe of Indians at Stockbridge. He then studied law, in 1753 was admitted to the bar, and practised at New Haven for the two following years. In 1775 he became pastor of the Second Church in Newport, R. I., and during his residence there found time for literary and scientific investigations, corresponding with learned men in almost every part of the world. His congregation at Newport being entirely broken up by the British occupation of the place, in May 1777 he removed to Portsmouth, N. H., to become pastor of the North Church. In September following he was elected president of Yale and shortly after professor of ecclesiastical history in connection with the presidency; and in June 1778 he entered on his official duties. After 1780 he discharged the office of professor of divinity. His labors for the college were intense and uninterrupted during the rest of his life. He was widely learned, being particularly versed in the Oriental languages. He published a funeral oration in Latin on Governor Law (1751); a Latin oration on his induction to his office as president (1778); an 'Account of the Settlement of Bristol' (1785); 'History of Three of the Judges of Charles I' (1795). His 'Literary Diary' in 45 volumes, was edited and published by F. B. Denton in 1901. His life has been written by J. L. Kingsley (in Sparks' 'American Biography,' first series, Vol. VI, 1845), and by Abil Holmes (Boston 1798).

STILETTO, a knife or dagger with a round pointed blade from 6 to 12 inches long, common in the Middle Ages.

STILICHO, stil't-kō, **Flavius**, Roman general: b. of Vandal origin about 359 A.D.; d. Ravenna, 23 Aug. 408. In 384 A.D. he was sent by the Emperor Theodosius on an important mission to Persia where he arranged a peace that was very advantageous to his sovereign and on his return in 384 was made commander-in-chief of the Roman army and given the hand of Serena, the niece of Theodosius, in marriage and with it several high titles and flattering official notice and the following year he was made commander-in-chief of the army in Thrace where he directed the war against the Picts, Scots, Saxons and the barbarians on the Hebrus. In 392 he carried on a very successful campaign against the Bostarnæ, Goths, Alani and Huns. In 394 Theodosius appointed Stilicho guardian of his son Honorius whom he had raised to the dignity of Augustus with

sovereignty over Africa, Gaul, Italy and Spain. But as the young man took little interest in affairs of state, this made Stilicho practical ruler of the Western Empire, which he defended against the invasion of the Goths under Rufinus, the guardian of the Empire of the East. He again repulsed the Germanic hordes in 406, and was the loyal servant of the empire in its foreign wars, defeating Alaric at Pollentia. He was accused of aiding Alaric in his encroachments upon the empire previous to its final conquest, and was obliged to flee from Rome. On the charge of high treason he was taken from the church at Ravenna which had given him shelter and executed. He was accused of plotting to put his own son upon the throne; which, it would seem, he came very near accomplishing. His distinguished services in behalf of Rome were commemorated by the poet Claudius. Consult Gibbon, 'Decline and Fall of Rome'; Hodgkins, T., 'Italy and her Invaders' (Oxford 1880); Villari, P., 'The Barbarian Invasions of Italy' (New York 1902).

STILL, Andrew Taylor, discoverer and founder of osteopathy: b. near Jonesboro, Va., 6 Aug. 1828; d. 12 Dec. 1917. With his father, Abram, Methodist minister and doctor, he removed to Tennessee, and at the age of nine to Missouri. At 19 he married Mary M. Vaughn and in 1853 they removed to Kansas, where Mrs. Still died in 1859. He farmed, studied medicine in Kansas City and practised among the pioneers and Indians with his father who had followed him. He fought with John Brown in the border warfare; was elected to the legislature in 1857; was one of the founders of Baker University at Baldwin, Kan. In 1860 he married Mary E. Turner, who lived until 1910. In the Civil War he served in the cavalry and afterward became captain and then major in the 21st Kansas Volunteers which saw considerable service. Ever a student of nature, he decided that the God who made man had placed in the body everything necessary for health, without the use of drugs. He studied the anatomy of the animals he skinned, and dissected many an Indian body in his search for truth. The war interrupted his investigations, but when three of his children died of spinal meningitis in 1864 he attacked the problem anew. In 1874 he announced the science of osteopathy (q.v.). For many years he waged a battle for recognition. For a while he practised as an itinerant doctor in Missouri, at times accompanied by one or more of his sons, and performed wonderful cures with his new science. In 1887 he settled in Kirksville, Mo., which had really been his home since 1875, and developed a large practice.

In November 1892, he opened the American School of Osteopathy, at Kirksville, which now gives a four-year course, and whose clinics and hospital draw patients from all over the United States as well as from Canada. Among his writings are 'Autobiography' (1897 and 1908); 'Philosophy and Mechanical Principles of Osteopathy' (1902); 'Osteopathy, Practise and Research' (1910).

RAY G. HULBURT,

Associate Editor, Journal of Osteopathy.

STILL, John, English ecclesiastic: b. Grantham, Lincolnshire, about 1543; d. Wells,

26 Feb. 1608. He was graduated from Christ's College, Cambridge, of which he was elected a Fellow, and took orders. In 1570 he became Margaret preacher and Margaret professor of divinity in the university. The next year he obtained the rectory of Hadleigh, Suffolk, and in 1572 became, with Dr. Thomas Watts, joint dean of Bocking, at the same time being appointed chaplain to the primate. In 1573 he was made vicar of East Markham and canon of Westminster, whereupon he resigned his Cambridge professorship. He was then promoted to be dean of Norwich and in July 1574 was elected master of Saint John's College, Cambridge. Having acted as vice-chancellor in 1575, he was in May 1577, transferred to the mastership of Trinity. In 1592 he was again elected vice-chancellor and was called upon to provide an English comedy for the queen's amusement. In 1593 he was consecrated bishop of Bath and Wells. The supposition that he was the author of 'Gammer Gurton's Needle' (q.v.) is highly probable. In 1575 the play published under the following title: 'A Ryght Pythy, Pleasant, and Merie Comedie: Intytuld Gammer Gurton's Needle: Played on Stage not long ago in Christes Colledge in Cambridge. Made by Mr. S., Master of Art,' and this Mr. S. can be identified with no one so naturally as with the vice-chancellor, Dr. Still, of the time. (See GAMMER GURTON'S NEEDLE). Consult Dodsley, 'Old Plays' (London 1874-76).

STILL, William, American philanthropist: b. Shamony, N. J., 7 Oct. 1821; d. 1902. He was of African descent; and became chairman and corresponding secretary of the Philadelphia branch of the Underground Railroad, 1851-61. Previous to this he had been a clerk in the Pennsylvania Anti-slavery Society from 1847. During the Civil War he was post-sutler at Camp William Penn for colored troops. He was very active in all movements to help colored people and was member of numerous societies organized to that end. He sheltered the wife, daughter and sons of John Brown while he was awaiting execution in Virginia. He published 'The Underground Railroad'; 'Voting and Laboring'; 'Struggle for the Rights of the Colored People of Philadelphia'.

STILL. See DISTILLATION.

STILL-LIFE, a branch of the art of painting which deals with the portrayal of lifeless objects. It is called in Germany, *Still Leben*; in Holland, *stilleven*; in France, *nature morte*; in Italy, *riposo*. The subjects generally chosen are dead animals—deer, birds or fish, kitchen and table utensils, plate, crockery or china, fruit, flowers, curios and jewelry. These objects are arranged so as to make a picturesque combination of color, light and shade. This branch of art flourished from the earliest days of color decoration, and was at its highest perfection during the Alexandrian age; the paintings at Pompeii and the Roman mosaics furnish many fine examples of it. The Renaissance painters did not execute still-life as an independent department of their art, but early in the 17th century it was cultivated most elaborately and with the greatest success by the Dutch school. The taste, beauty, and exquisite virtuosity of their work have never been surpassed, if ever even equaled. There are two

main styles of still-life painting. While some artists have endeavored, by a certain breadth and freedom of handling, to obtain a mere decorative effect by the introduction of brilliant metallic surfaces and the juxtaposition of rich color tones, others have aimed at minute and painfully elaborated compositions, fine and delicate as a miniature on parchment or ivory. The chief Dutch painters of still-life are J. Brueghel the elder, Snijders, Leegers, the de Heem family, A. van Beijeren, W. Kalf, Heda, W. van Aelit, Dou and Fyt. In the 19th century a great revival took place in this class of art. In France it was practised successfully by Robie, Vollon, and Ph. Rousseau; in Germany by Preyer of Düsseldorf; Hoquet of Berlin; P. Meyerheim, Hertel, Th. and R. Grönland, and by the woman painters Begas-Parmentier, H. von Preuschen, Hormuth-Kallmorgen, and Hedinger. The still-life of flowers and fruit is generally most successfully accomplished in water colors. The ancient Greek painter Pausias was especially skilful in the representation of flowers, while of another ancient artist it is said that the birds flew down and picked at his picture of fruit. Among the American painters who have been successful in depicting still-life are W. M. Chase, E. Carlsen and W. Lockwood.

STILLE, Alfred, American physician: b. Philadelphia, Pa., 30 Oct. 1813; d. there, 24 Sept. 1900. He studied at Yale University in 1828-30, was graduated at the University of Pennsylvania in 1832 and took his M.D. there in 1836. He studied in Paris and Vienna subsequently at different times after engaging in practice in Philadelphia. He was resident physician at the Pennsylvania Hospital in 1839-41; professor of the theory and practice of medicine at the Pennsylvania Medical College in 1854-59, and at the University of Pennsylvania in 1864-84, afterward being professor emeritus there. He was lecturer on clinical medicine at the Philadelphia Hospital in 1865-71. He was one of the founders of the American Medical Association and became its first secretary, serving as president in 1867. He was one of the first to distinguish typhus from typhoid fever, and attained high rank in his profession both as practitioner and as teacher. Author of 'Medical Instruction in the United States' (1845); 'Therapeutics and Materia Medica' (2 vols., 1860); 'Epidemic Meningitis' (1867), etc. He was joint editor of the *National Dispensary* (1879).

STILLE, stîl'ê, Charles Janeway, American educator and historian: b. Philadelphia, Pa., 23 Sept. 1819; d. 11 Aug. 1899. He was graduated from Yale in 1839 and was admitted to the bar, but abandoned law for literature. In the Civil War he was a member of the United States Sanitary Commission, and in 1866 was made professor of history and English literature in the University of Pennsylvania. He was provost there (1868-80). He published 'Historical Development of American Civilization'; 'History of the United States Sanitary Commission' (1866); 'Studies in Mediæval History' (1882); 'Beaumarchais and the Lost Milton' (1886).

STILLINGFLEET, Edward, Anglican bishop: b. Cranborne, Dorset, 17 April 1635; d. Westminster, 28 March 1699. He was gradu-

ated at Saint John's College, Cambridge, in 1652 and was elected to a fellowship there in 1653. He was appointed chaplain to Charles II in 1668, dean of Saint Paul's in 1678 and became bishop of Worcester in 1689. He was famous for his profound learning, his liberal views and for his untiring efforts to effect a satisfactory compromise between Episcopacy and Presbyterianism. He was brilliant as both a preacher and a writer, and in his lifetime exerted a wide influence. Author of 'Irenicum' (1659); 'Origines Sacrae, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures' (1662); 'Origines Britannicae, or Antiquities of the British Church' (1685), etc. His collected works were published (6 vols., London 1710).

STILLMAN, Samuel, American Baptist clergyman: b. Philadelphia, Pa., 18 March 1738; d. Boston, Mass., 12 March 1807. He was ordained in the Baptist ministry in 1759, and in 1765 became pastor of the First Baptist Church, Boston, which pulpit he occupied for more than 40 years. He was among the most influential preachers of his day in New England. He was one of the original trustees of Brown University, and was a member of the convention that ratified the United States Constitution in 1788. Author of 'A Sermon on the Repeal of the Stamp Act' (1766); 'Thoughts on the French Revolution' (1794); 'A Sermon Occasioned by the Death of George Washington' (1799), etc.

STILLMAN, stil'man, Thomas Bliss, American chemical engineer: b. Plainfield, N. J., 24 May 1852; d. 1915. He was graduated from Rutgers College in 1873 and went to Germany to study engineering and analytical chemistry. Returning to the United States he was appointed instructor of analytical chemistry at Stevens Institute (1874-76), and was professor there 1881-86. In 1884 he was state oil inspector for New Jersey. He was editor of the 'Stevens Institute Indicator' (1895-98) and has published 'The Rutgers Scarlet Letter' (1873); 'Engineering Chemistry' (1897); 'Examination of Lubricating Oils' (1914).

STILLMAN, William James, American author: b. Schenectady, N. Y., 1 June 1828; d. Surrey, England, 6 July 1901. After graduation from Union College (1848) he studied landscape art with F. E. Church, and in 1849 went to England to continue his art-work. He adopted the views of Rossetti and Millais, whence he was styled "the American Pre-Raphaelite." On return to the United States he began exhibiting at the Academy of Design, of which in 1854 he was made an associate. In 1852 he went for Louis Kossuth to Hungary to secure the crown-jewels which had been secreted by Kossuth at some point on the Danube. After some further study with Yvon at Paris, he came back to found with John Durand, the *Crayon*, a magazine of art criticism, which continued two years (1855-57). In 1859 he was again in England and in 1861-65 was United States consul at Rome, and in 1865-69 he held a similar post in Crete. Having abandoned art, owing to failing eyesight, he was a special correspondent for the *Times* of London from 1878 to 1898, traveling widely about the continent, and being from 1886 correspondent for Italy and Greece. In 1883-85

he contributed critical papers on art subjects to the New York *Evening Post*. An expert photographer, he was at one time associate editor of the *Photographic Times*. He made for the Hellenic Society of London a valuable series of photographs of the Acropolis at Athens, and published (1872-73) two manuals of photography. As a journalist he wrote much on many subjects, chiefly art, history and politics, and gained a considerable reputation. His best picture is 'The Procession of the Pines' (1858). Among his published volumes are: 'History of the Cretan Insurrection' (1874); 'Herzegovina and the Late Uprising' (1877); 'On the Track of Ulysses' (1887); 'The Union of Italy' (1898); 'The Old Rome and the New' (1898); 'Francesco Crispi' (1899); and an interesting 'Autobiography' (Boston 1901, first printed in the 'Atlantic' 1900).

STILLWATER, stil'wá'tér, Minn., city, county-seat of Washington County, on Saint Croix River, 30 miles from its junction with the Mississippi River, and on the Chicago, Milwaukee and Saint Paul, the Northern Pacific and the Chicago, Saint Paul, Minnesota and Ohio railroads, about 18 miles northeast of Saint Paul. It has steamer connections with the river ports and regular connection with Dubuque and Saint Louis. It was settled in 1840, and incorporated as a city in 1854. The Saint Croix River boom, through which pass each year about 300,000,000 feet of pine logs, is north of and near the city. Stillwater is in an agricultural region, and is extensively engaged in manufacturing. The chief industrial establishments are flour and feed mills, grain elevators, lumber mills, foundries, machine shops, carriage and wagon works, and furniture factories. The city has a large trade in logs, lumber and lumber products, wheat, flour and livestock. It is the commercial and industrial centre of the Saint Croix lumber region in Minnesota and Wisconsin and has grain elevators, machine shops, foundries, breweries, brickyards, boat and wagon factories. The educational institutions are a high school, public and parish elementary schools, private business schools, two convents, the Minnesota State prison, and the Carnegie library. The government is vested in a mayor and council of nine members, three of whom are elected each year. Stillwater was first located on the plain bordering on Lake Saint Croix, with bluffs outside the settled portion. Now the old part of the city is given up to trade and manufacturing houses and the residential portion is on the bluffs. Pop. about 11,000.

STILLWATER, Battles of. See SARA-TOGA, BATTLES OF.

STILLWELL, Lewis Buckley, American electrical engineer: b. Scranton, Pa., 12 March 1863. He was educated at the Wesleyan and Lehigh universities, and in 1886 established himself in New York as a consulting electrical engineer. He was chief engineer of the Westinghouse Electrical Company in 1891-97; electrical director of the Niagara Falls Power Company in 1891-1900; of the Rapid Transit Subway Construction Company in 1900-08, and consulting electrical engineer to the Manhattan Railroad Company in 1900-04, and to the Hudson Company from 1904. He was president of

the American Institute of Electrical Engineers in 1909-10.

STILT, or **FROST-BIRD**. See **SAND-PIPER**.

STILTED ARCH, in *architecture*, an arch which does not spring immediately from the imposts, but from a vertical piece of masonry resting on them, so as to give the arch an appearance of being on stilts. Arches of this kind occur frequently in all the mediæval styles.

STILTS, wooden poles with steps or foot supports at a sufficient distance from the ground to allow a person standing on the steps to walk with long strides. Stilts are very useful in marsh lands and were formerly very popular in the French Landes. In various European countries stilts are used by the peasants for crossing streams.

STIMSON, Frederic Jesup, American lawyer and author, known also by the pen-name 'J. S. of Dale': b. Dedham, Mass., 20 July 1855. Graduated from Harvard in 1876 and from the law school of the institution in 1878, he entered practice in Massachusetts and was assistant attorney-general of that State in 1884-85. He was secretary to the National Conference on the uniformity of law in 1892; was made counsel to the United States Industrial Commission, and lectured at Harvard on legislation. He published 'Stimson's Law Glossary'; 'American Statute Law'; 'Handbook to the Labor Law of the United States' (1896); 'Labor in its Relation to Law' (1896); and in fiction, among several other works, 'Guernedale' (1882); 'The Crime of Henry Vane' (1883); 'The Residuary Legatee' (1887); 'First Harvest' (1889); 'King Noanett' (1896); 'Jethro Bacon of Sandwich' (1901); 'In Cure of her Soul' (1906); 'The American Constitution' (Lowell Institute Lecture, 1906); 'The Law of the Constitutions, State and Federal' (1907); 'Popular Law-making' (1910); 'The Light of Provence' (poem-play); 'My Story: An Imagined autobiography of Benedict Arnold' (1917).

STIMSON, Henry Albert, American Congregational clergyman: b. New York, 28 Sept. 1862. He was graduated from Yale in 1885, and studied in the Unión and the Andover Theological seminaries. He has held pastorates in several American cities including New York; is a lecturer at the Chicago Theological Seminary; and has published 'Religion and Business' (1894); 'Questions of Modern Inquiry' (1894); 'The Apostles' Creed' (1899); 'The Right Life' (1905); 'The New Things of God' (1908); 'Behind the World and Beyond' (1910); 'While the War Raged' (1914); and many articles in magazines and newspapers. Was recording secretary of the American Board of Commissioners for Foreign Missions (1881-1915); vice-president, American Missionary Association and American Tract Society; director of Seaman's Friend Society and American Bible Society; president of Board of Visitors, Andover Theological Seminary; trustee of Carleton College, Drury College and Mount Holyoke College; director, Chicago Theological Seminary and Hartford Theological Seminary; president, Congregational Board of Ministerial Relief; president of Congregational

Annuity Fund for Ministers; vice-president, Congregational Church Extension Society; and president of Congregational Church Building Society. Has degrees of M.A., and S.T.D., from Yale and D.D., from Ripon.

STIMSON, Henry Lewis, American lawyer and cabinet officer: b. New York, 21 Sept. 1867. He was graduated at Yale University in 1888, at Harvard in 1889 and at the Harvard Law School in 1890. He was admitted to the bar in 1891 and engaged in practice in New York. He became a member of the law firm of Root and Clarke in 1893, of Root, Howard, Winthrop and Stimson in 1897 and of Winthrop and Stimson in 1901. He was United States district attorney for the southern district of New York in 1906-09; unsuccessful candidate for governor of New York in 1910, and in 1911-13 he was Secretary of War under President Taft. He was a delegate to the New York State Constitutional Convention in 1915.

STIMSON, John Ward, American artist: b. Paterson, N. J., 16 Dec. 1850. He was graduated from Yale in 1872, and from École des Beaux Arts, Paris. He became lecturer and art teacher at Princeton University, and was for four years director of the art schools of the Metropolitan Museum of Art, New York. He founded the Artist-Artisan Institute, New York, 1888, and later became director of the Art and Science Institution, Trenton, N. J. He is a brother of Henry Albert and Lewis Atterbury Stimson. He is a popular lecturer on art, and has published 'The Law of Three Primaries'; 'Principles of Vital Art Education'; 'The Gate Beautiful'; and 'Wandering Chords.'

STIMSON, Lewis Atterbury, American surgeon: b. Paterson, N. J., 1844. He was graduated from Yale University in 1863 and received the degree of M.D., from the same institution in 1874. He served as captain in the Union army during the Civil War. In 1893 he was a Regent of the University of the State of New York, and is professor of surgery in Cornell University (1904). He has published: 'Operative Surgery' (1900); 'Fractures and Dislocations' (1900).

STIMULANTS, agents which temporarily increase the vital activities, either in particular organs and functions or in the whole physical organism. They are among the most valuable and important of medicines, and perhaps are more often the direct means of saving life than any others. But as they are powerful, their injurious effects, when misapplied, have been even more prejudicial to mankind than their best use has been beneficial. In fact it may be said that the abuse of this class of medicines, under the names of cardiacs, cordials, alexipharmics, etc., caused more deaths during the dark ages of medicine than did sword and pestilence united. The dreadful mortality of smallpox and fevers during the Middle Ages, and even as far down as the earlier parts of the 19th century, was mainly owing to the administration of heating stimulants, the tendency of which was to increase the violence of the disease, although they were intended merely to expel noxious and poisonous humors. But by a more cautious use of these articles they are the means of preserving life. Stimulants are

either simple and direct in their operation, as the external application of heat in all forms, dry and moist, by friction, etc.; the application to the stomach of hot liquors, spices, camphor, hartshorn, warm and aromatic gums and oils, as mint, cardamon, cajeput, ginger, asa-fœtida, red pepper, spirits of turpentine, etc.; or they act first as stimulants, but produce afterward effects of a different character, as is the case with wine, brandy and spirits of all sorts; opium, ammonia, ethers, etc., all of which are highly stimulant at first, and in small quantity, but afterward, and when taken in larger doses, produce exhaustion, debility, sleep and death. The first class are upon the whole the safer, and should always be used in preference to the last when they can be had, in cases of suspended animation from cold, drowning, suffocation, etc.; while the others are more valuable for their secondary and remote effects, by means of which they ease pain, and relieve spasm and other affections; and for these purposes they should be used freely, as they can do no hurt while the violence of the disease persists. But they should never be resorted to unless pain is urgent, or debility become so great as to endanger life.

STINDE, stin'dě, **Julius**, German humorist: b. Kirch-Nüchel, in the eastern part of the province of Holstein, 28 Aug. 1841; d. Olsberg (bei Kassel), Westphalia, 7 Aug. 1905. He attended the gymnasium at Eutin, near his native village, became an apothecary in 1858, and then attended the universities of Kiel, Giessen and Jena to study chemistry. For several years he served (1863-66) as a chemist attached to factories, but made simultaneous attempts to enter journalism. From 1864 to 1868 he was editor of the *Hamburger Gewerbeblatt*, from 1865 to 1875 of the *Reform*. He resided in Berlin after 1876. His stories of Berlin life depict the commercial lower middle class of the large cities, especially in communities that are expanding successfully. His most successful types are the members of the Buchholz family, who, in their life at home, and in their travels in Italy and elsewhere, retain constantly the coarse but healthy humor that is characteristic of their class, with that certain Berlin or metropolitan superciliousness which is as unmistakable as it is unpleasant. So successful was Stinde's exploitation of their foibles, that he settled down to a sort of factory production, turning out nothing but repetitions of the same types, which never failed to yield the expected financial return. Among his best known stories are 'Buchholzens in Italien' (1883; 54th ed., 1905); 'Die Familie Buchholz' (3 vols. 1886; 87th ed. 1905); 'Frau Buchholz im Orient' (1889); 'Frau Wilhelm Buchholz' Memoiren' (1895); 'Hotel Buchholz' (1897). His comedy on the same subject, 'Bei Buchholzens' (1900), was not a success. Consult Cherbuliez, 'Profils étrangers' (Paris 1889); Meyer, R. M., 'Die Ahnen der Familie Buchholz' (Berlin 1905).

JACOB WITTMER HARTMANN.

STINESS, **John Henry**, American jurist: b. Providence, R. I., 9 Aug. 1840; d. 3 Sept. 1913. He graduated at Brown University in 1876; studied law, admitted to the Providence bar (1868) and practised law there until he was

appointed judge of the Supreme Court of Rhode Island, 1893. He was a member of the Rhode Island House of Representatives (1874-75), and Associate Justice (1875-1900); and Chief Justice of the Supreme Court of Rhode Island (1900-04); has written 'History of Lotteries in Rhode Island' and 'Liquor Legislation in Rhode Island'; 'Civil Changes in the Senate.'

STING, a weapon possessed by many plants and small animals, in various forms, employed to pierce and in most cases also to poison, the flesh of animals to be killed for food, or from which injury is received or expected. In plants this office is performed by stiff, sharp, hollow hairs emitting an acrid juice. (See **NETTLE**.) Such stinging-hairs sometimes cause extreme irritation in the skin and mucous membranes of even the largest animals, and hence cause the plants to be avoided, thus protecting the species against harm. The simpler marine animals (*Coelenterates*) are widely defended by stinging instruments, consisting of coiled poison-carrying threads which dart from microscopic capsules in the surfaces of the integument. (See **NEMATOCYSTS**; **JELLY-FISH**.) Insects are plentifully provided with piercing weapons. These in some cases are mouth-parts and in others are modified ovipositors. To the first class belong the sharp prolonged jaws, many plant-sucking bugs, or blood-sucking ones, such as the bed-bug, cone-nose (qq.v.) and others. In another group are found the gnats and mosquitoes, which inflict pain upon large creatures and death upon minute ones by stabbing with their complicated beaks, which consist of a bundle of lancets and saws. (See **MOSQUITO**.) Many caterpillars are defended by nettle-like hairs, each of which is a specially modified spine and able to inflict so great annoyance that hairy caterpillars generally are studiously avoided by most animals. The "sting," properly speaking, however, is found among insects only in the hymenoptera, as bees and wasps, where it is a modified ovipositor (q.v.). In wasps (q.v.) it serves a special purpose in paralyzing the insects stowed away alive with the eggs in the nest cells. Spiders are said to "sting," but in reality they bite, in some cases, poison. Scorpions, however, possess what is properly enough termed a sting in the pointed telson or tail-piece appended to the extremity of the abdomen, with which a poison-infected puncture is inflicted (see **SCORPION**). Some fishes, as the sticklebacks, surgeon-fish, and notably the sting-rays (q.v.), has certain defensive spines, by which highly irritating wounds may be inflicted. The use of the fangs by poisonous snakes, also is often spoken of as stinging.

STING-RAY, or **STINGAREE**, **STING-GOREE**, a fish-ray of the family *dasyatida* remarkable for the long, flexible, whip-like tail, which is armed near its root with an erectile spine or spines, very sharp at the point, and furnished along both edges with sharp cutting teeth. It inflicts a painful, poisonous wound. In some of the numerous members of this family, two or even three spines are bundled together. In Great Britain the sting-ray is called the fire-flare, or sometimes fiery-flare. In the United States it is often called the clam-cracker. See **RAY**.

STINK-BUG, any of several small heteropterous plant-feeding bugs, allied to the squash-bugs, which emit a vile odor. The name is generally applied to the common squash-bug.

STINK-HORN FUNGUS. See **FUNGI**.

STINK-POT, a malodorous kind of box-turtle (q.v.).

STINKING MAY-WEED. See **FENNEL**.

STINKWOOD, a tree (*Oreodaphne foetida*) of the family *Lauraceæ*, a native of the Cape of Good Hope, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish and resembles walnut. It has been used in shipbuilding.

STINT. See **SANDPIPER**.

STIPA, feather-grass; an important genus of grasses (q.v.).

STIPEND, a payment at stated periods for services rendered, and generally used in connection with official or ecclesiastical salaries. It is not officially used, however, except in Scotland, where the provisions for the support of the parochial minister of the established church is designated as a stipend.

STIPENDIARIES. See **MERCENARIES**.

STIPPLE ENGRAVING. See **ENGRAVINGS**.

STIPULES, in botany, are organs connected with the leaves, existing only in the dicotyledonous plants. They are small scale-like or leafy appendages at the point where the leaves come off from the stem, and are commonly in pairs, there being one on each side of the petiole, as in the hornbeam and lime. They are more frequently free, not being attached to the petiole; but sometimes they are united to the base of that organ, as in the genus *Rosa*. The stipules afford excellent characters for the arrangement of plants. When a vegetable of a natural order has these organs, it is very seldom the case that all the others are not equally provided with them. Thus they exist in all plants of the natural orders *Leguminosæ*, *Rosaceæ* and *Tiliaceæ*. As they fall off very easily when they are free, their absence might sometimes induce one to suppose a plant destitute of them, but this error may be avoided by observing that they always leave on the stem, at the place where attached, a small cicatrix, which attests the fact of their having existed. They vary greatly in their nature and consistence. They may be foliaceous or leaf-like, as in the common agrimony; membranous, as in the fig and magnolia; spinescent or thorny, as in the jujube and gooseberry. Some fall off before the leaves, as in the common fig and the lime; others are merely deciduous, or fall at the same time as the leaves; and there are others which continue for a longer or shorter time after the leaves have fallen, as in the jujube and gooseberry. The use of the stipules appears to be to protect the leaves before their expansion, as is evidently shown by their relative disposition in the buds of some orders of plants. See **LEAVES**.

STIRLING, Edward Charles, Australian anthropologist: b. Strathalbyn, South Australia, 8 Sept. 1848. He was educated at Cambridge University and London where he graduated in

medicine. He became lecturer in London; but returned to South Australia in 1881 as professor of physiology in the University of Adelaide, consulting physician at the city hospital and director of the South Australian Museum. He was a member of the House of Assembly, 1883-86. His published works include 'Anthropology of Central Australia'; 'The Horn Scientific Expedition'; and a vast amount of scientific work contributed to journals and magazines.

STIRLING, James Hutchinson, Scottish philosopher: b. Glasgow, 22 June 1820; d. 1909. He was educated in arts and medicine in Glasgow University, France and Germany; and practised as a surgeon in Wales for some years, but ultimately devoted himself to travel, study and literary and philosophical pursuits. He is the author of 'The Secret of Hegel' (1865); 'Sir Wm. Hamilton, being the Philosophy of Perception' (1865); 'Jerrold, Tennyson, Macaulay and other Essays' (1868); 'As Regards Protoplasm' (1869); 'The Philosophy of Law' (1873); 'Burns in Drama, together with Saved Leaves' (1878); 'Text-book to Kant' (1881); 'The Community of Property' (1885); 'Philosophy and Theology' (the Gifford Lectures, 1890); 'Darwinianism, Workmen and Work' (1894); 'What is Thought?' (1900); 'The Categories' (1903); and translator of Schwegler's 'History of Philosophy,' and Kant's 'Critique of Pure Reason in his Text-book to Kant.' Consult Stirling, A. H., 'James Hutchinson Stirling' (London 1912).

STIRLING, John William, Canadian oculist, aurist and surgeon: b. Halifax, Nova Scotia, 2 July 1859. He was graduated in medicine at the University of Edinburgh in 1884 and later studied at the universities of Berlin and Vienna. He engaged in practice in Montreal in 1887 as an ophthalmological and aural surgeon. Since 1906 he has been professor of ophthalmology at McGill University. He is also oculist and aurist to the Montreal General Hospital and surgeon oculist to the Royal Victoria Hospital. Author of numerous papers on ocular diseases.

STIRLING, William Alexander, EARL OF, Scottish poet and colonial proprietor: b. about 1567; d. London, 12 Sept. 1640. He was educated at Glasgow and in Germany. His tragedy 'Darius' was published in 1603, and was followed by three others, 'Cæsar', 'The Alexandrian Tragedy,' and 'Julius Cæsar,' which were collected under the title, the 'Monarchicke Tragedies,' in 1607. He also wrote a number of sonnets, but is best known as a recipient from James I of a grant bestowing upon him, under the name of Nova Scotia, the whole of the eastern portion of Canada, and the patent of sole printer for 31 years of King James' version of the Psalms. The conquests of France in Canada, however, deprived him of practically all of his grant. Consult Charles Rogers, 'Memoirs of the Earl of Stirling and the House of Alexander' (1877).

STIRLING, Yates, American rear admiral: b. Baltimore, Md., 6 May 1843. He was graduated at the United States Naval Academy in 1863, and in 1863-65 served on the *Shenandoah* in the North Atlantic blockading squadron, participating in both actions at Fort Fisher.

He was promoted commander in 1880, captain in 1894 and rear-admiral in 1902. He was commandant of the naval station at San Juan, Porto Rico, in 1900-02; of the navy yard in Puget Sound in 1902-03; commander of the Philippine squadron of the Asiatic fleet in 1903-04, and of the cruiser squadron of that fleet in 1904, while in 1904-05 he was commander-in-chief of the Asiatic fleet. He was retired upon reaching the age limit in 1905.

STIRLING (formerly **STRYVELYNE** or **ESTRIVELIN**), a river-port, city and county in Scotland: (1) county-seat of Stirlingshire, on the south side of the Forth, 29 miles northeast of Glasgow. It occupies a commanding site, Castle Hill, resembling its namesake at Edinburgh. The castle is of great historical interest. It contains the rooms where Douglas received a mortal stab from James II, who, as well as James V was born in this castle; and the Parliament-house, chapel-royal. The view from the battlements comprehends many of the lochs and fertile vales of Scotland, the winding river and the Grampian and Ochil hills, together with the ruins of Cambus-Kenneth Abbey and the Bridge of Allan. Within the town, Greyfriars Church, begun by James IV, museum, library, picture-gallery, several ancient mansions and monuments deserve notice. The manufactures of the town include: woolen, cotton and linen goods, carpets, leather, malt, soap, mineral oils, ropes and carriages. The salmon-fisheries are profitable. There is little trade. Pop. about 22,000. (2) Stirlingshire is a county of South Scotland with an area of about 466 square miles. About one-third of the county is hilly, and rises in Ben Lomond to a height of about 3,000 feet. Here the Forth flows into the Firth of Forth, coming from Ben Lomond. The southeastern portion is traversed by the Forth-Clyde canal. The famous Loch Katrine forms one of the numerous lochs or lakes. The valleys and plains are exceedingly fertile and highly cultivated. There are a few marshy lands. The country is rich in minerals, especially iron and coal. The chief industries in addition to those mentioned in connection with the city of Stirling are the working of the mines. The chief towns besides the capital are Falkirk, Grangemouth and Kilsith. Consult 'History of the Chapel Royal of Stirling' (published by the Grampian Club); and 'The Charters of Stirling' (by same as above).

STIRLING'S PLANTATION ON BAYOU FORDOCHE, Engagement at. On 5 Sept. 1863, General Herron's division of the Thirteenth corps, General Banks' army, embarked on transports at Carrollton, La., and sailed up the Mississippi to disperse a Confederate force under Gen. R. Taylor, which was then on the west side, below the mouth of Red River, seriously threatening the navigation of the river. Morgan's Bend was reached on the 7th, from which point, on the morning of the 8th, about 200 cavalry and a brigade of infantry, under Col. H. M. Day, moved out on a reconnaissance toward the Atchafalaya River, and encountering the Confederate pickets, drove them across the Atchafalaya and then fell back three miles. On the 9th Day was joined by General Herron, with another brigade, and a second reconnaissance was made to the Atcha-

falaya, where there was a smart skirmish, and Herron fell back to the river, with a loss of a few men killed and wounded. On the 12th the cavalry was again sent to the front to feel the enemy, and the 19th Iowa, 26th Indiana and two guns were sent out seven miles to the vicinity of Atchafalaya Bayou to picket the country and support the cavalry. All were under command of Lieut.-Col. J. B. Leake, of the 20th Iowa. Leake had a skirmish with the enemy and fell back to Stirling's Plantation, on Bayou Fordoché, about six miles from Morganza, from which point he sent out parties daily, which skirmished with the Confederates. On the night of the 28th Gen. Thomas Green, with two brigades of Confederate infantry, one of cavalry and mounted infantry, and a battery, crossed the Atchafalaya, and by different routes reached the rear and flanks of Leake's command, by marching through swamps and canebrakes, and about noon of the 19th fell upon his unsuspecting camp. The cavalry was soon driven from the field, and managed to escape with small loss; the infantry made a gallant stand and fought desperately, but attacked on all sides, were soon overpowered and captured, with the two guns. Leake was severely wounded. The Union loss was 16 killed, 45 wounded and 454 missing or captured; the Confederate loss, 26 killed, and 85 wounded. Consult 'Official Records' (Vol. XXVI).

STIRNER, stêr'nér, Max, German philosopher, a pseudonym for JOHANN KASPAR SCHMIDT, b. Bayreuth, 25 Oct. 1806; d. Berlin, 26 June 1856. His reputation is based upon a single book, 'Der Einzige und sein Eigentum' (1845, English tr. 'The Ego and his Own,' by S. T. Byington, London 1913). After completing his gymnasium course in his native town (1819-26), he attended the University of Berlin (1826-28), where he heard lectures chiefly on philosophy and theology under Hegel, Schleiermacher, Neander, Marheineke and others. His next university was that of Erlangen (1828-29), which he left for that of Königsberg, not attending any lectures at the latter institution, however, for "family reasons," the nature of which is not known, any more than the manner in which he distributed his time between Königsberg and Kulm in East Prussia (the new home of his parents) in 1830-32. The year 1832-33 was again spent at the University of Berlin, after the completion of which he applied for a certificate as a teacher in Prussian gymnasiums. He wrote two papers as part of the requirement for this position, one on Thucydides, the other on the School Laws, the latter showing considerable revolutionary spirit. He served as teacher in training (*Probekandidat*) without pay at the Berlin Königliche Realschule for a year and a half, and married Agnes Burtz (1815-38), who (with her child) died in childbirth after a very short marriage. Stirner seems to have kept away from government institutions after his first experience in teaching, and obtained a position in the Girls' School of Madame Gropius (later the Misses Zepp), in Berlin, which he held from 1839 to 1844. Little is known of his life, beyond the data given above. For several years after 1841 he was the most regular attendant at the meetings of an irregular organization known as "Die Freien" (The Free), which met in Hippel's Weinstube

on Friedrichsstrasse and elsewhere, none of the other members of which attained much fame. A few occasional visitors to the place expressed themselves unfavorably as to its rather loose tone. Karl Marx, who was present once, never met Stirner, as the latter joined after Marx's departure. Stirner married, as his second wife (21 Oct. 1843), Marie Dähnhardt (1818-1898?), who after his death asserted that he had deceived and neglected her, and who probably had little understanding for his philosophical work. They separated in 1846, after which time Stirner led an irregular life in furnished rooms. The house in which he died (Berlin NW, Philippstrasse 19) has been marked with a tablet since 1898.

Stirner's great work, 'The Ego and His Own,' met with sensational success on its first publication (1845), but passed into a relative oblivion, and did not again attract attention until the superficially similar philosophy of Nietzsche began to be widely read (about 1895). It is a work in excellent aphoristic style, apparently an anarchistic attack on all human society, on co-operation and institutions of every kind, on the human race itself. Obedience to any form of authority is derided, respect for the traditions of the past scorned. The Ego is the supreme law, external obligations and submissions to them are concessions to the "spooks" with which the world is infested. Laugh at them, and they melt away. A careful reading will convince the reader, however, that Stirner was not an anarchist, and that his propaganda was an attack on those ideological compulsions (church, state, monarchy, etc.) that are not based on the real needs of humanity, and displays a considerable analogy with the destructive portions of the social criticism of Karl Marx (whose 'Deutsch-französische Jahrbücher' the book quotes unfavorably), without any of the latter's constructive method. All of Stirner's other writings seem to have been chiefly general literary work: a translation of Adam Smith's 'Wealth of Nations' (4 vols.), of the French economist Jean Baptiste Say's 'Handbuch der praktischen politischen Ökonomie' (4 vols.), and an original work: 'Geschichte der Reaktion' (2 vols. 1852), which sketches the practices of the reactionary classes following the French Revolution as well as of the same classes in the German Revolution of 1848. Robert Gieseke (1827-1890) published a novel, 'Moderne Titanen' (Leipzig 1850), of which Stirner is the hero (under the name Horn). Consult Adler, M., 'Wegweiser: Studien zur Geistesgeschichte' (Stuttgart 1914); Carus, P., 'The Predecessor of Nietzsche' (Chicago 1911); Mackay, J. H., 'Max Stirner' (Berlin 1910); Messer, M., 'Max Stirner' (Berlin 1907); Ruest, A., 'Max Stirner' (Berlin 1906); Zocchi, E., 'I gruppi anarchici degli Stati Uniti e l'opera di Max Stirner' (Modena 1901); Stirner, M., 'Kleinere Schriften,' ed. by J. H. Mackay (Berlin 1907).

JACOB WITTMER HARTMANN,
Assistant Professor of the German Language
and Literature, College of the City of New
York.

STIRRUP, an article of equestrian equipment with which the ancients were not acquainted. The Roman youth were accustomed to leap upon their horses sword or lance in

hand. Distinguished persons and old men had servants to place them on their horses, and conquered sovereigns were often compelled to perform this office for their vanquishers.

STITCHWORT, plants of the genus *Alsine*, belonging to the pink family, *A. (Stellaria) holostea*, most properly bears the name. It is an Old World species, an erect, but low, hardy perennial, with slender stems and opposite grass-like leaves, which are sessile and usually glabrous. The flowers are five-merous, the petals deeply cleft, and are showy, being three-fourths of an inch wide and very numerous. They are gathered in leafy panicles and fairly cover the plants with bloom. For this reason stitchwort is cultivated as a border plant. It was reputed to be a cure for a "stitch in the side" and even for snake-bites. It has many other names, as shirt-buttons, all-bone and snap-jack, the latter referring to its brittle nodes.

STITH, William, American colonial historian: b. Virginia, 1689; d. Williamsburg, Va., 27 Sept. 1755. He studied theology, was ordained in England to the ministry of the Established Church, was chaplain of the Virginia house of burgesses, and in 1752-55 rector of Henrico parish and president of William and Mary College. He published a 'History of the First Discovery and Settlement of Virginia' (1747), which De Tocqueville criticised as "long and diffuse," but it is nevertheless a standard work on early Virginian history, and written with excellent scholarship. It was the only published instalment of an extended work planned by the author, and reaches as far as the dissolution of the London Company. It is prepared from the colonial archives, Sir John Randolph's papers, the 'Records' of the London Company, and the Byrd library. It was re-edited and published with a biography in 1866.

STIVER, a former Dutch coin and money of account worth about two cents.

STOAT, 'The British name of the common European weasel.'

STOBEÆUS, Johannes, Greek grammarian and critic: b. Stobi, Macedonia, of the latter half of the 5th century. For the education and improvement of his son Septimius, he compiled a florilegium of Greek literature, for which he drew upon about 500 Greek poets, historians and philosophers. This has formed one of the most precious legacies which ancient scholarship has bequeathed to posterity. His works contain citations and quotations from many lost works and have been of immense assistance to modern Greek criticism. The original work was composed under the single title 'Anthologion,' but the scholars of the Middle Ages divided it into two parts 'Eclogæ Physicæ et Ethicæ' and 'Florilegium,' which were edited by Gaisford and published at Oxford, the former in 1825; the latter in 1850. There is a good edition of his works published by Wachsmuth and Hense (Berlin 1884-1909). Consult Christ-Schmid, 'Geschichte der Griechischen Literatur' (Munich 1913).

STOCK. See BATHOLITH.

STOCK, a popular name for several species of cruciferous flowering plants long favorites in gardens. The Virginian stock (*Malcomia maritima*) is a hardy annual herb which grows

wild in the Mediterranean region. It is of simplest culture and will thrive well in cities without apparently impairing its beauty or fragrance. The common autumnal queen, or Brompton stock (*Matthiola incana*) is a biennial or perennial semi-woody herb or sub-shrub, a native of the Mediterranean region and the Isle of Wight. The intermediate or ten-weeks stock (*M. incana*, var. *annua*) is considered by some botanists to be a distinct species, but except for its annual habit it differs little from the preceding and is, therefore, ranked as a variety. Both are known as gilliflower or gellyflower and are widely cultivated for their variously colored, deliciously fragrant flowers which in many varieties are double. The latter usually are sown very early and successionally so as to bloom during the early summer months; the former are planted somewhat later so as to continue the blossoming into the autumn. They are about as easy to grow as geraniums and require fairly rich friable garden soil, good drainage, but plenty of moisture, and clean cultivation. There are about 30 other species, some of which are cultivated and several of which are fragrant only at night.

STOCK (Anglo-Saxon, *stocce*, post, trunk, stick) *in law*, represents the capital of corporations and is usually divided into shares of a definite value denoting the rights in the assets, profits and management of the company possessed by the members of the corporation or the persons contributing the capital. A certificate of stock is a mere evidence that the person therein designated is entitled to an interest in the company, which is stated. Shares of stock may be of any value the company sees fit to set, and the par value may not, and in fact, generally is not the selling price of the stock. In the United States some States have a law requiring stock to be issued at its par value. Stock may be divided into several classes, for example, as common and preferred; holders of the common stock have an equal right in the company and its profits; holders of the preferred stock are entitled to a preference over other shareholders but they are not creditors of the corporation. Dividends on stock represent a division of the surplus or net profits arising from the business of the company. Stock is considered as personal property and may be transferred at the will of the owner by proper assignment of the certificate. This is generally done by having the name of the purchaser of the stock placed legally upon the books of the company in the place of that of the seller. The purchaser of stock from a stock-owner should have his name entered at once on the books of the company to prevent fraud on the part of the seller who might have the name of some one else entered. This would stand good, in so far as the company was concerned. (See STOCKHOLDER; STOCK EXCHANGE; CORPORATIONS). Consult Cook, 'Treatise on the Law of Corporations' (Chicago 1903); Dos Passos, 'The Law of Stock Brokers and Stock Exchanges' (New York 1905). The capital stock of a company is the amount fixed by the charter of a corporation as the sum already paid or to be paid into its treasury for use in the carrying on of its business operations. This does not include the actual property owned by the corporation or company.

STOCK BREEDING, the art of producing and rearing domestic animals, particularly those of greater agricultural value known as farm live stock, including cattle, horses, pigs, sheep and fowls. The successful practise of this art depends upon an intimate knowledge of the particular kind of stock to be bred and a familiarity with certain general principles applicable to the breeding of stock of various kinds. The special knowledge of each kind of live stock can best be obtained by actual farm experience under skilled supervision but much useful information can be obtained from live stock manuals, which describe the breeds of farm animals and their management. To impart such information is also the aim of courses of instruction in animal husbandry and poultry management given in agricultural colleges.

General Principles.—The discovery of general principles applicable in stock breeding is a work to which agricultural experiment stations are appropriately giving much attention. Investigators in universities and research institutions have made important contributions in this field through their studies of variation and heredity. See article GENETICS.

To propagate any kind of animal successfully the breeder should know its life history thoroughly, under what climatic conditions it attains sexual maturity or becomes sexually active, what is its period of gestation or incubation, at what age full size and productiveness are attained, when senility begins, what are the best feeds and how to prepare them, and other similar facts.

The successful breeder will employ all knowledge of this sort which he possesses in controlling and utilizing the activities of his animals to serve the purpose which he has in mind. What that purpose is will determine both the choice of foundation stock and his management of it. For example, breeding cattle for milk production, for butter making, for cheese making or for beef require in each case a different choice of foundation stock and different management of it.

The question of when and how man acquired domestic animals, while of little present practical concern, has much scientific interest. A complete answer to it might show whether domestication of other animals is likely to occur in the future and if so under what conditions. Its solution would also throw much light on the early history of man and the rise of civilization. Present knowledge indicates that man as distinct from other primates originated in Central Asia and at first utilized for food and clothing wild plants and wild animals, as the most primitive races of mankind still do. Later, plants began to be cultivated and animals kept and reared in captivity to insure more dependable supplies of food and clothing. In Asia man domesticated the dog, sheep, goats, the ass, cattle, horses and pigs. All of our more important farm animals originated with man in his old home, Central Asia, in a remote, prehistoric period. With man they were taken in migrations into Europe and Africa. The migration of man into America from Asia occurred undoubtedly at a very early period. The dog was the only domesticated animal that came with the emigrants from Asia to America. Pos-

STOCK BREEDING

1 Raleigh's Oxford Prince, A. J. C. C. 123167. Grand Champion Jersey Bull at the National Dairy Show, Columbus, Ohio, 1918. Bred, raised and exhibited by Edward C. Lasater, Falkurria, Texas. 2 Great Scot's Champion, A. J. C. C. 263703. Grand Champion Cow at National Dairy Show, Chicago, 1911. Register of Merit, record 11,138.6 lbs. milk and 774 lbs. 4 ozs. of butter, in her 13th year. Owned by Edward C. Lasater, Falkurria, Texas. 3 First Prize Breeders' Young Herd, at National Dairy Show, Columbus, Ohio, 1917, bred and exhibited by Edward C. Lasater, Falkurria, Texas. This is the most coveted prize of any show; the herd consists of one bull, two yearling heifers and two heifer calves, all bred and exhibited by owner.

sibly this migration occurred before other animals had as yet been domesticated, certainly no others were brought over. A considerable degree of civilization was acquired by man in the American hemisphere quite independently of the development of civilization in the Old World, but all the many food plants cultivated here by the natives, as well as their few domestic animals (except the dog), were indigenous. The cultivated food plants of American origin include many of the world's best, such as maize and potatoes, but the domestic animals are of little consequence, including only the llama, alpaca and guinea-pig. That man in America developed so many good food plants but such unimportant domestic animals shows that the available material in one case was excellent, but in the other case was poor. Conversely the pre-eminent success of man in central Asia in securing what are still our best domestic animals shows what paleontology confirms, that herbivorous animals suitable for easy domestication were abundant in the early home of man and were in fact early domesticated. They have been much modified subsequently and many diverse breeds have been produced in consequence of the supervision which man exercised over their racial evolution. The study of breeds of domestic animals afforded to Darwin some of the most convincing evidence for his theory of organic evolution by descent with modification from simpler and less specialized ancestors. As compared with their wild ancestors, domestic animals have undergone modification through the agency of selection, sometimes exercised consciously and with the definite end in view of perpetuating new and useful variations, sometimes obtained incidentally and without set purpose. Conscious selection for breeding purposes of the most docile individuals and of those which were strong and vigorous has in general given to domestic animals tameness and docility, making them easy of management. It has also given them early maturity which is usually accompanied with fecundity. Unconscious or natural selection would also favor variations toward early maturity and fecundity, since such variants in a mixed herd would naturally leave most offspring. Indirect effects of increased tameness and gentleness are greater and more economical consumption of food and more ready fattening, with decline in intelligence unless specially selected for as in the case of the dog and the saddle horse. Products of special utility have by selection been greatly improved or intensified and thus breeds kept for special purposes have originated. Examples are seen in the great milk production of dairy cattle and milch goats; of wool production in sheep and the alpaca, of meat production in pigs, mutton sheep and beef cattle. Under the guiding influence of selection continued through untold centuries breeds of domestic animals have become machines of the greatest efficiency for the production in maximum quantity of a specialized product of supreme quality. No more convincing evidence can be produced of the effectiveness of selection in guiding evolution in useful directions than is afforded by a study of breeds of domestic animals.

Present Day Methods.—The method of the present day breeder is that of all his predecessors

who more or less consciously and intelligently have worked for the improvement of domestic animals. The method is to select in each generation and to rear offspring from those animals which are best suited to the special purpose for which the breed is kept, be it milk, meat, wool, work or what not. Thus breeds for special purposes are created and further improved. But the work of the animal breeder is less simple than this statement might seem to imply, since in the production of a new generation of animals *two* parents are involved, each of which influences the character of the offspring. Each selection of animals for propagation thus involves a double selection, selection of a sire and selection of a dam, and it is not sufficient that each be excellent for its kind. The two must be compatible in the inherited traits which they transmit. Otherwise undesirable combinations of characters may be obtained in the offspring, or a lack of the desired uniformity in different individuals.

The breeder's first principle of success is accordingly (1) *Select the best individuals to breed from.* His second principle is (2) *Mate each selected animal with one having compatible characters.* This in general will mean the mating of like with like, selecting mates only within the same established breed or sub-breed. But here comes in a danger which must be avoided. If animals most like each other in inherited traits are mated together, brother will be mated with sister, or cousin with cousin. But age-long experience shows that such matings very often result in diminished vigor, size or fecundity and so the careful breeder is reluctant to resort to close inbreeding, and if he does so occasionally in order to secure or preserve some particularly desirable combination of characters, he takes special precautions to avoid enfeebling effects. The breeder's third principle is accordingly (3) *Avoid close inbreeding.* No one can tell in advance to what extent inbreeding may safely be followed in a particular case. Miss King, experimenting with rats, has found it possible, by selecting in each generation only the most vigorous individuals to breed from, to continue mating brother with sister for more than 20 generations, without loss of vigor or fecundity in the race. On the other hand, rats inbred without such selection for vigor as was made by Miss King show marked loss of vigor and fecundity after 10 or 15 generations. He who resorts to inbreeding should do so with caution, keeping careful watch of the size and vigor of his race. Crossbreeding, i.e., the mating together of unrelated individuals, or those of very different inherited characters, has an effect on vigor contrary to that of inbreeding. It increases size and vigor and induces rapid growth. This is an important principle utilized by animal breeders in meat production among cattle, sheep and pigs. Distinct breeds are crossed, such as short-horn and Angus cattle, or Berkshire and Duroc-Jersey pigs. The result is to produce an animal superior to either pure breed as regards rapid growth and early maturity. But this superiority persists for a single generation only, so that the production of a second generation from the vigorous cross-breeds is not to be recommended. Lack of uniformity both in vigor and in other characters is quite sure to occur in the second generation, though not in

the first. A fourth maxim for the breeder would be (4) *Employ crossbreeding whenever practicable, to increase vigor, but do not go beyond the first cross.*

While the variable second crossbred generation is of little use to the ordinary breeder, it may be of great value to the experimental breeder, who is engaged not in mere quantity production of a standard type of animal, as the ordinary breeder is, but in the attempt to produce a new type of animal better suited for some special purpose than are existing types. The experimental breeder works by the method of crossing two breeds, each of which contains a different inherited character or set of characters, which he desires to combine in one new race. Crossbreeding is the only method by which characters found in different races may be combined in a single new race. Seldom is the desired combination secured in the first crossbred generation. More often it will only be found in a small percentage of the second generation crossbreds obtained by breeding first generation crossbreds with each other. Such animals of the second generation crossbreds as do present the desired combination of characters may now be mated with each other and a new race of the desired type may thus be secured. But at first it is apt to be rather variable and several additional generations of selection are usually required fully to establish the new type. The production of a new breed is thus a difficult and expensive undertaking and should be tried only by experts familiar with the method of inheritance of different characteristics.

The fundamental law of inheritance which underlies character recombination in new breeds, and to which also established breeds owe their uniformity, is known as Mendel's law (q.v.). This is the law of unit character inheritance, in accordance with which the different inherited characters are found to behave like independent units in transmission and so can be rearranged in new combinations. Each individual of an established breed of animals transmits a certain assemblage of inheritance units, which constitute the breed characteristics. So long as matings are made only within the breed all the progeny have these same inherited breed characteristics, such as black color and hornlessness in the case of Aberdeen-Angus cattle, red color and hornlessness in the case of Red Polled cattle, red color and horns in the case of Devon cattle, and white face and horns in the case of Hereford cattle.

But if we cross a breed of black cattle with a breed of red cattle, the first generation offspring will be black, the color unit black being stronger than the color unit red. We call black the *dominant* unit of the two, and red the *recessive* unit. But the black crossbreds have inherited red no less than black, even though they do not show it, and they will transmit it to half their progeny the alternative with black being transmitted to the other half of the progeny. Accordingly if a crossbred black bull is mated with red cows, we find that on the average half the calves are black in color and half are red. This comes about as follows: The crossbred bull transmits the black unit to half his calves. This unit meets a red unit transmitted by the red dam and dominates it producing a black calf. To the

remaining calves, half of the total, the bull transmits the red unit which meets a red unit transmitted by the red dam and thus produces a pure red combination. Such reds will breed true because they contain *only the red unit*. But the blacks which contain also a red unit will not breed true. Nevertheless true breeding blacks may be obtained even from crossbreds, by mating black with black. If the crossbred black bull were mated with pure black cows, half his calves would be pure blacks, viz., those to which he transmitted the black unit, for to all the calves in such matings the black dam would transmit the black unit. If the crossbred bull were mated with crossbred cows, one-fourth of the calves would be pure blacks, two-fourths would be impure blacks (not true breeding) and one-fourth would be pure reds. For each parent would transmit impartially either the black or the red unit and the expected combinations would be:

Units transmitted by sire, B or R
Units transmitted by dam, B or R

Combinations	BB, Pure black	BR, BR, Impure black	RR Pure Red
--------------	-------------------	-------------------------	----------------

If the two breeds of cattle which we crossed were Aberdeen-Angus and Red Polled, all the cross-bred calves would be polled, since both breeds possess this same unit. But if we crossed Aberdeen-Angus cattle, which are black and polled, with Devon cattle, which are red but have horns, we should get a different result, viz., imperfectly developed horns (scurs) in the crossbreds, which would all be black. A crossbred bull of this sort would transmit to half his calves the polled condition and to half he would transmit horns. To half he would transmit black color and to half he would transmit red color. But horns and color are distinct units in heredity, hence the *combinations* of units which a crossbred of this sort might transmit would be of four sorts, viz., polled black, polled red, horned black and horned red. In fact animals presenting these four sorts of combinations would be obtained in the second generation of crossbreds produced by mating first generation crossbreds with each other. This case illustrates how the principle of unit character inheritance may be utilized to secure new combinations of inheritance units in which breeds differ. The maximum number of recombinations may be obtained in the *second* crossbred, not the first crossbred, generation. This principle has undoubtedly been utilized, consciously or unconsciously, in producing existing breeds and can be used more freely in the future because its operations are now better understood. Nevertheless the crossing of breeds is something which should be undertaken cautiously, for it will be found that few cases are as simple as the hypothetical one just discussed. Most breeds differ by a great many unit characters and a cross in such cases produces an extremely variable second generation, because of the large number of recombinations of characters which will be obtained, and few of these recombinations, even if desirable, can be isolated in true breeding types without subsequent selection through several generations.

Moreover most inherited characters are not simple (behaving as single units) but complex, depending upon the simultaneous presence of

several or many independent units. This makes their manipulation in crosses extremely difficult. Differences in size, early maturity and productiveness are among the most valued economic characters of breeds, yet these in no case behave as simple units in transmission. They commonly behave neither as dominant nor as recessive units but yield intermediates or blends. A second crossbred generation again yields blends but with increased variability, giving indications of segregation more or less complete. This is interpreted as meaning that many distinct units are involved which segregate and recombine independently of each other. In such cases crosses are useful only if the production of intermediates is desired. If it is desired to extend the range of existing variation in quantitative characters, it is better not to cross breeds, but to practise systematic selection in the desired direction within the breed which most nearly approaches the ideal. For example, suppose increased quantity production of milk is desired in cattle. The most productive of existing breeds is admitted to be the Holstein-Friesian. If this breed is crossed with a less productive breed, the offspring are found to be of intermediate productiveness. Such a cross would not be a promising means of obtaining productiveness greater than that of the Holstein-Friesian. It would be better to search within the breed for families of unusual productiveness and try further to improve these best families by selection, avoiding close inbreeding however by mating with each other representatives of different families of great excellence. This is the practise now followed by the best informed breeders. Still there are conditions under which crossbreeding, even of Holstein-Friesian cattle, may be desirable. Holstein milk contains too little butter fat to satisfy some markets. Improvement in its quality may be secured by a cross with dairy breeds which produce richer milk, though less of it, as is true of Guernseys and Jerseys. Whether the improvement in quality thus secured will offset the diminished quantity production entailed by the cross and the undesirable variability of the later crossbred generations is a matter for experimental determination.

A fifth maxim for the breeder may now be formulated. (5) *Both the uniform excellence of established breeds and the making of new breeds with novel combinations of characters depend upon Mendel's law of unit character inheritance. The breeder should be thoroughly familiar with the workings of this fundamental law.*

STOCKADE, (1) *In civil engineering* a row of piles, or a series of rows, driven into a sea or river shore, to prevent the erosion of the banks. (2) *In fortification*, stout timbers planted in the ground so as to touch each other and loop-holed for musketry. In its most effective form it is eight or nine feet high, has a ditch in front and a banquette in the rear. The stockade is a very old form of fortification. See FORTIFICATIONS.

STOCKBRIDGE, Henry, American lawyer; b. North Hadley, Mass., 31 Aug. 1822; d. Baltimore, Md., 11 March 1895. He was graduated at Amherst College in 1845 and was admitted to the bar in 1848. He was a special district attorney in the service of the War Department of the United States in the Civil War; and in 1864 was a member of the Maryland legislature, where he introduced the bill which resulted in convening a constitutional convention and the abolition of slavery in the State. Later he successfully combated in the United States courts the indentures of apprenticeship through which emancipation was being evaded. He was for more than 20 years vice-president of the Maryland Historical Society and editor of its fund publications. Author of 'Archives of Maryland' (1886).

STOCKBRIDGE, stök'brij, Mass., town, Berkshire County, on the Housatonic River, and on the New York, New Haven and Hartford Railroad, 15 miles south of Pittsfield. The town includes the villages of Stockbridge, West Stockbridge, Centre, Curtisville and Glendale. In 1736 the Stockbridge Indian mission was moved here from Great Barrington, and under the influence of this mission the Indians were civilized and Christianized, so that, in 1739, when the town was incorporated they were given full privileges of citizenship. In 1751 Jonathan Edwards became pastor of the church. After the Revolutionary War the Indians moved west, finally settling in Kansas. The town is situated in the midst of picturesque mountain scenery, and contains many handsome summer residences. It has a number of mills, including woolen, paper, grist and saw mills; and a national bank, a public high school founded in 1868 and a public library, founded in 1862. Pop. about 2,000. Consult Jones, 'Stockbridge Past and Present.'

STÖCKER, stök'ër, Adolf, German theologian and social reformer; b. Halberstadt, 11 Dec. 1835; d. 1909. After studying theology and philology in Halle and Berlin, he was made pastor at Seggerde (1863) and eventually court and cathedral preacher at Berlin. His importance is owing to the fact that in opposition to the Social-Democrats he founded, in 1877, a Christian Socialistic party. This new association won numerous adherents in only a few places, but the idea of Christian Socialism has been widely accepted by a large number of re-

ligious teachers. In his fiery zeal and activity against his opponents he was particularly violent in his treatment of the Jews, and he thus hindered the practical success of his theory. In 1880 he was elected to the Reichstag and allied himself with the extreme conservatives. But his socialistic activity, by which he was led more and more to take the attitude of reforming agitator, displeased the government and in 1890 he was dismissed from his office of court-preacher. He was president of the Berlin City Mission; Member of the Upper Synod; and in 1892 became editor of the 'Deutsche Evangelische Kirchenzeitung.' He is the author of a volume of 'Sermons for the People' as well as of 'Speeches.' He has also published many Socialistic tracts and an autobiography.

STOCKHOLDER. A stockholder is one who owns stock in a corporation or joint stock company, and who has been vested with certain rights and liabilities by law, by virtue of his relation to other owners of stock and to creditors of the corporation. The term shareholder is used commonly interchangeably with stockholder. When a corporation is formed and the books of the company are opened, individuals subscribe for stock or shares in the company and certificates are issued to them as evidence of their right in the company which is granted by virtue of the sale of stock, the certificates of stock being merely the evidence of the transaction. Loss of certificates, or the fact of their not being issued cannot relieve the owner of stock of his rights, or of his liabilities. Although stock may be paid for in services, or good will, or patents, or property, as well as in money or negotiable paper, the stockholders as soon as they acquire membership in the corporation stand on the same footing, and have equal privileges. The number of shares owned regulates the proportion of interest to be drawn by the individual, and the voting power in the affairs of the company. Any person who has legal capacity to own personal property may be a stockholder, and municipal and private corporations may be stockholders in other corporations within limitations contained in their incorporation. A manufacturing corporation may not subscribe to the stock of a bank or of a railroad, but may in payment of a debt, take stock in such other corporation, and may hold it and enjoy the same rights as other stockholders. The rights of all stockholders are represented by the corporate management, usually a board of directors. Legal relation between the corporate management and the shareholders is created by subscribing to, or contributing for shares of stock. The stockholder relies entirely upon the charter of the corporation as to his contract, regardless of representations of an agent, and an alteration in the constitution effecting a radical change in the corporate enterprise releases a shareholder from his subscription. A corporation has the right, through its management, to carry on the corporate enterprise as against all persons including a minority of the shareholders, in a manner and for the purposes set forth in its constitution. The board of directors can be controlled only by action of a majority of shareholders. It is understood that the majority of shareholders shall govern in all matters coming within the act of corporation, and all shareholders are bound by

the acts of the majority represented by the management. The individual shareholder has only that control of the affairs of the corporation which his vote represents at the meetings of shareholders. If it may be shown that any act of the corporation will benefit a majority of shareholders, one shareholder or a minority, may not interfere, because the act may be an injury to him. But a minority may prevent by law any use of the funds of the corporation which are not strictly within the charter, or which may be shown as detrimental to the majority. Shares of stock give the holder a fixed right in the division of the profits or earnings of the company so long as it exists, and of its effects when dissolved. At corporate meetings each shareholder has a right to vote, and this cannot be taken from him. The right to vote by proxy does not exist unless so stated in the constitution of the company. Each holder has the right to inspect the company books either personally or through a representative or attorney.

It is supposed that stock is paid for at par and that the number of shares sold represents the working capital of the corporation. A creditor may enforce his right to have the nominal value of capital stock paid in, even to making the directors call upon the stockholders to pay a pro rata share on their stock. The liability of a stockholder for the debts of the company is fixed by statute and differs in the various States. In some States a stockholder can be held for a sum equal to his subscription; special liabilities which make the stockholder responsible for other amounts or for particular debts, also exist under the laws of some of the States. Regarding the liability of shareholders in a national bank, it has been held that the shareholders are individually responsible, equally and ratably, and not one for another, for all contracts, engagements and debts of such association to the extent of the amount of their stock therein, at the par value thereof, in addition to the amount invested in the shares.

Irregular or fraudulent transfers may be set aside if it can be shown that there was intention to escape liability to the detriment of creditors.

A subscriber to stock is presupposed to know the obligations assumed and ignorance will not excuse him from liability to creditors. See CORPORATIONS, HISTORY OF; STOCK; EXCHANGE.

STOCKHOLM, stök'hölm, capital of Sweden, situated on the Mälars See (Lake Mälars), 440 miles southwest of Saint Petersburg. It is on a cluster of islands, connected with the mainland by bridges, chief of which are the Norrbrö and Vasabro, joining the stadtn or city with the north side of the strait. The city, without its northern accessories, might impress one as another Venice, especially

1 The Royal Palace, Stockholm

2 General view of Stockholm

in approaching it from the Baltic or from Moseback Hill. Yet it surpasses in natural attractions the Venetian city. The largest island is Gustavsholm, containing the city proper; and with the islands of Riddarsholm and Helgeandsholm, is the oldest section. Its antiquity and irregularity render this part most interesting. Other islands contain the modern-constructed town. The houses are frequently coated with stucco in light colors or white. The buildings of note are the palace of the 17th century, with Corinthian pillars adorning the façade, and an edifice of symmetrical proportions. The National Museum, the Northern Museum, the Riddarhus (Knight's house) and several churches. The oldest church is Saint Nicholas (1264), in which Swedish sovereigns are crowned; the Riddarsholm Kyrka, contains the remains of a long line of kings and has other historical interest. In Norrmalm is the church of Adolphus Frederick and the National Library, containing 250,000 books, and 8,000 manuscripts. On the northern mainland stands the National Museum, a fine Renaissance edifice, which contains many antiquities, coins, drawings, engravings, etc. There are, too, the governor's house, facing the quay where an obelisk commemorates Gustavus III; the Ridderhus or Senate Chamber; the Rigsdagshus or House of Parliament; exchange, mint, town-house, with courts of law; ethnographical museum with numerous Scandinavian antiquities; theatres, opera-house, arsenal and barracks. There is a medical college, technological institute, navigation school, school of design, also benevolent institutions and other educational establishments; literary, scientific and artistic associations, etc. Chief among the latter are the Swedish Academy, Academy of Sciences, celebrated by the name of Berzelius; musical academy; medical, horticultural and agricultural societies. Ship-Island, east of the city island, is headquarters of the Swedish navy, and contains ship-building yards and marine repair-shops. Farther east are the islands containing the zoological gardens. All the islands have communication with each other by bridges, tramways and steamboats. The recreation grounds and promenades are attractive, especially Djurgården, Haga Park and Carlberg. The city's manufactures are chiefly textiles, porcelain, pottery, sugar, tobacco, cotton, ironware, beer, soap, food products and machinery. Trade is considerable, Stockholm, being the largest Swedish industrial and commercial centre and its most important port of entry, and the principal exports are: iron, copper, tar and timber. The imports: colonial produce, wine, salt, fruit, etc. The shipping of Stockholm is second highest in the kingdom and shipbuilding is one of the industries of the city. There were, in 1908, 249 vessels engaged, with a total tonnage of 124,037. Stockholm was founded in 1260. Subsequently fortified, it withstood several memorable sieges. Pop. about 400,000.

STOCKHOLM, Bank of. As this was the earliest bank to issue circulating notes, an outline of its history can scarcely fail to prove of practical value. After the death of Gustavus Vasa his daughter, the Regent Christina, 1632-45, was compelled by the embarrassments of the treasury to issue a sort of exchequer-bill, which appears to have had a somewhat slow

and grudging circulation as money. Ten years later the treasury, still embarrassed, adopted the suggestions of a financier named Palmstruck and established a bank at Stockholm in 1656, which invited deposits of coins, bullion and runstyks, for which it granted transferable credits on its books in "Bank-money"; an expedient which met the approval of the commercial community. In 1658 the bank began to issue "transport-notes" which being more convenient than copper runstyks soon drove the latter into the bank, which now being upon an avowedly copper basis, began to lose credit as bullion copper fell in value and the copper plates to support the transport-notes became too heavy for convenient circulation. In this dilemma Baron George Heinrich de Goertz, the king's financial adviser, closed the mints to the "free coinage" of copper and issued light copper dalers (dollars) instead. But the government was too weak to sustain a fiduciary currency; the pieces were too inartistic to defy counterfeiting, and there was no fixed limit to their emission, three cardinal requirements of such a currency, especially the third one. The inevitable consequence was a ruinous fall in their value, a rise of popular indignation against Baron Goertz, his impeachment, trial, condemnation and unjust execution 3 March 1719. The bank (Rigsbank) is still in existence. (Consult 'History of Monetary Systems,' 298). For list of other ancient banks see list under the heading BANKS AND BANKING.

STOCKING, a covering for the foot and leg, knitted or woven either from cotton, woolen or silk thread. The stocking is made usually only of one thread entwined so as to form a species of tissue, extremely elastic, which readily adapts itself to the part it is intended to cover. The tissue differs from cloth in having neither warp nor woof, but approaches it closely, and is much superior for the purposes to which it is applied. The ancients wore no particular covering for the legs, but during the Middle Ages, hose or leggings of cloth came into use; and at a later period the art of knitting stockings was invented, according to some authorities by the Spaniards, while some attribute it to the Scots. In 1589 William Lee of Nottinghamshire, England, invented the stocking-frame, a machine for weaving stockings which was in use and scarcely improved upon for nearly two centuries. Lee met with little encouragement in his attempts to set up an establishment in England and went to France where he was received with great favor by Henry IV. The monarch's assassination soon after, however, interrupted his prospects and he died in Paris in great poverty. A knowledge of his machine was carried back to England by some of his workmen who established themselves in Nottingham, which has since remained the principal seat of the English hosiery manufacture. For the stocking-frame and improvements in stocking machinery, and for modern methods of manufacture, see **HOSIERY AND KNIT GOODS INDUSTRIES IN THE UNITED STATES.**

STOCKPORT, stōk'pōrt, England, in the counties of Cheshire and Lancashire, on the Mersey River, five miles southeast of Manchester. It stands upon an elevation, in terraces, is irregularly built, but highly picturesque.

There are churches of various denominations, the chief of which are Saint Mary's, Saint Thomas', Saint George's, Saint Peter's, Saint Paul's and Christ Church. Other noteworthy buildings are the Mechanics' Institute, market-hall, free library, technical and grammar schools and infirmary. The museum is situated in Vernon Park, one of the several recreation grounds of the city. The railway viaduct on the London and North-Western Railroad is of fine proportions and spans a great part of the town. The staple manufacture is cotton. There are numerous factories and industrial works, including print, dye and bleach works, and extensive hat factories, iron and brass foundries, breweries and brickyards. The city owns the street railway, electric-light plant, markets, gas, water-power and sewage works. Pop. about 110,000.

STOCKS, a wooden apparatus to put the legs of offenders in, formerly used for the restraining of disorderly persons, or as a punishment for certain offenses.

STOCKTON, Charles G., American physician: b. Madison, Ohio, 27 Aug. 1853. He was graduated in medicine at Buffalo University in 1878. He was professor of materia medica and therapeutics at Niagara University in 1885-87; and has been professor of medicine and clinical medicine at Buffalo University since 1887. He is attending physician at the Buffalo General Hospital; and consulting physician at the New York State Hospital for Crippled and Deformed Children. He has contributed to various medical compilations and encyclopedias, and is author of 'Diseases of the Stomach.'

STOCKTON, Charles Herbert, American rear-admiral: b. Philadelphia, Pa., 13 Oct. 1845. He was graduated at the United States Naval Academy in 1865, first having seen active service in the Civil War on the *Macedonian*. He was promoted commander in 1892, captain in 1899 and rear-admiral in 1906. He commanded the *Yorktown* in 1895-97; was president of the Naval War College in 1898-1900; commanded the *Kentucky* in 1901-03; was naval attaché at the American embassy, London, in 1903-05; and commanded the Special Service squadron visiting Bordeaux, France, for the maritime exposition in 1907. He was retired in 1907. He was president of the George Washington University in 1911-13; and was the first United States delegate to the London Naval Conference in 1908-09. He has written extensively on international law and besides numerous papers is author of 'A Manual of International Law' (1911); 'Outlines of International Law' (1914), etc.

STOCKTON, stök'ton, Francis Richard, (Frank R. Stockton), American author: b. Philadelphia, Pa., 5 April 1834; d. Washington, D. C., 20 April 1902. After a secondary education in Philadelphia, he became a wood-engraver, practised the art with some success, and invented a double graver (1866). In 1872 he entered journalism, joining the staff of the *Philadelphia Post*, in the same year that of *Hearth and Home* of New York, somewhat later that of *Scribner's Monthly*, and in 1874 that of *St. Nicholas*, of which he was assistant editor until 1882. During this period he wrote

many stories for children, among which were 'Roundabout Rambles' (1872); 'What Might Have Been Expected' (1874); 'Tales Out of School' (1875); 'A Jolly Fellowship' (1880); 'The Floating Prince' (1881); 'The Story of Viteau' (1884) and 'Personally Conducted' (1889). His first success was made with 'Rudder Grange' (1879), a burlesque account of a house-boat outing, and this he followed by the now well-known series of quaint and whimsical volumes which have made Stocktonian humor a thing peculiar to itself. Much of his best work is to be found in his short stories, the best known of which is probably 'The Lady or the Tiger.' He was a prolific writer of novels, short stories, sketches and tales for children. Much of his humor depends upon the situation in which his characters are placed and the grotesque attitude of the author toward them; yet Stockton created many delightful characters that, with all their whimsicality, are quite human and very likeable personages. The list of his published works includes 'The Casting Away of Mrs. Lecks and Mrs. Aleshine' (1886); 'The Late Mrs. Null' (1886); 'The Christmas Wreck' (1886); 'The Bee Man of Orn' (1887); 'The Dusantes' (1888); 'Amos Kilbright' (1888); 'The Great War Syndicate' (1889); 'The Squirrel Inn' (1890); 'Ardis Claverden' (1890); 'The Watchmaker's Wife' (1893); 'The Adventures of Captain Horn' (1895); 'The Girl at Cobhurst' (1897); 'A Story Teller's Pack' (1897); 'The Associate Hermits' (1898); 'Afield and Afloat' (1900); 'A Bicycle of Cathay' (1900); 'John Gayther's Garden, and the Stories Told Therein' (1902) and 'The Captain's Toll-Gate' (1903). See **CASTING AWAY OF MRS. LECKS AND MRS. ALESHINE; RUDDER GRANGE**.

STOCKTON, Richard, American statesman: b. near Princeton, N. J., 1 Oct. 1730; d. there, 28 Feb. 1781. He was graduated from the college of New Jersey, at Newark, in 1748, studied law, was admitted to the bar in 1754 and rose rapidly to the first rank as a lawyer. In 1776 he visited England. He was made a member of the executive council of New Jersey in 1768 and in 1774 was appointed a judge of the Supreme Court. In 1776 he was elected to Congress and, though at first doubtful of its policy, cordially supported the Declaration of Independence. In the same year he served on the committee appointed to inspect the northern army and report its state to Congress. After his return to New Jersey was captured by the British and confined in the common prison at New York. The unusual severity with which he was treated there broke his strength and eventually caused his death. Consult Sanderson, J., 'Biography of the Signers of the Declaration of Independence' (Philadelphia 1847).

STOCKTON, Robert Field, American naval officer and politician: b. Princeton, N. J., 20 Aug. 1795; d. there, 7 Oct. 1866. He served in the War of 1812 and in the Algerian war 1814-15. In 1821 he commanded the *Erie* on a cruise to Africa, where he secured the territory which now forms the present Liberian republic; and in the autumn of the same year he was instrumental in the suppression of pirates and slavers in the West Indies. He strongly advocated a steam navy and drew the plans for

the sloop of war *Princeton* on which an exploding gun killed the secretaries of war and the navy in 1844. He was commander of the Pacific squadron during the Mexican War, when he took possession of California in the name of the United States, capturing Los Angeles and San Diego and establishing civil government on the coast. After his resignation from the navy in 1850 he devoted himself to politics and in 1851 was elected to the United States Senate, where he introduced a bill, subsequently passed, abolishing flogging in the navy. On leaving the Senate in 1853 he turned his attention to the improvement of the Delaware and Raritan Canal, an enterprise he had previously encouraged. Consult 'Life and Speeches of Robert Field Stockton' (Philadelphia 1856).

STOCKTON, Thomas Hewlings, American Methodist Protestant clergyman, half-brother of F. R. Stockton (q.v.): b. Mount Holly, N. J., 4 June 1808; d. Philadelphia, Pa., 9 Oct. 1868. He began the study of medicine but in 1829 entered the ministry of the Methodist Protestant Church. He was chaplain to the House of Representatives in 1833-35 and in 1859-61. He had charge of churches at Philadelphia in 1838-47; at Cincinnati in 1847-50; at Baltimore in 1850-56; and again at Philadelphia in 1856-68. He was a pioneer in anti-slavery agitation, an opponent of sectarianism and was famous for his eloquence. He compiled a hymnbook for the use of his denomination, and was author of 'Sermons for the People' (1854); 'Poems, with Autobiographic and other Notes' (1862); 'The Book Above All' (1870), etc.

STOCKTON, Cal., city, the metropolis and chief distributing centre of the San Joaquin Valley, county-seat of San Joaquin County; 78 miles east of San Francisco and 397 miles northwest of Los Angeles.

Transportation and Commerce.—Stockton is favorably situated to command the trade of the San Joaquin Valley and of the mining and lumbering districts along the eastern rim of the valley. The main lines of the Atchison, Topeka and Santa Fé and the Western Pacific and two lines of the Southern Pacific run through Stockton, connecting it with San Francisco and its bay region, the San Joaquin Valley to the south, the Sacramento Valley to the north and eastern points. Branch lines of the Southern Pacific extend from Stockton to the mining regions on the Mother Lode and the lumbering districts of the Sierra. One hundred and seventeen passenger trains daily enter and depart from Stockton. The Yosemite Valley, the Tuolumne Grove of Big Trees, the Calaveras Big Trees, Mercer's Cave and Lake Tahoe are readily reached by automobile from Stockton; Yosemite Valley and Lake Tahoe also being connected by rail. The city is at the head of all-the-year navigation on the San Joaquin River system, being connected to the river by a navigable channel two and one-half miles in length. To San Francisco by water is 94 miles and daily steamer service is maintained. The leading articles, in the order of their valuation, are general merchandise, millstuffs and grain, potatoes, barley, beans, vegetables, wheat, horses, sheep, vehicles, lumber, onions, fuel oil, machinery and canned goods. Since the beginning of the grain industry of California,

Stockton has been the principal grain market of the great central valley. The 14 grain and produce warehouses of Stockton have an aggregate capacity of 165,000 tons and there are another 10 warehouses in the outside districts which bring the aggregate storage capacity up to 200,000 tons. All of the local warehouses are conveniently located to handle shipments by both rail and water. Grain is transported from Stockton to ocean vessels in San Francisco Bay for 65 cents per ton. Forty-nine commodities are shipped annually from Stockton in carload lots, the most important being agricultural implements, grain, beans, engines, flour and millstuffs, hay, livestock, onions, potatoes, wine, brandy, grapes, fruits and leather.

Manufactures.—Abundance of raw material, cheapness of power, low transportation rates and location as a distributing centre have developed the manufacturing interests of the city, and there are 157 manufacturing establishments in Stockton, with an annual output valued at \$11,293,000. Fuel oil from the upper San Joaquin Valley is the most common source of power. With fuel oil at recent current prices, power can be generated in Stockton as low as one-half of a cent per horse-power per hour. Electricity, coal and gas are also used as sources of power. From the source of power on the Mokelumne River, 45 miles distant, a line with the capacity of 30,000 horse-power delivers electricity in Stockton for lighting and manufacturing purposes. A second line of the capacity of 6,000 horse-power extends from the south fork of the American River to Stockton, a distance of 80 miles. Fourteen natural gas wells, varying in depth from 1,800 to 3,000 feet, supply gas for home and factory use. This city is the centre of the flour, cereal, poultry and dairy feed industry of the State. The mills have a daily capacity of 2,000 barrels of flour, 1,500 barrels of cereals, 100 tons of poultry and dairy foods and 600 tons of by-product foods. Large export shipments are made to the Orient, Europe, Alaska, Central and South America and the Southeastern States. "Caterpillar" and "sieve-grip" traction engines, combined harvesters, rice harvesters, seed cleaners, pumps, plows, harrows, scrapers and other agricultural machines and implements are manufactured in Stockton. Stockton has the largest traction engine plant west of the Mississippi River and its product is shipped to every country in the world. This combined harvester factory covers approximately nine acres and is the largest of its kind in the world. This type of machine combines header and threshing machine, cutting, threshing and sacking the grain by continuous process. The so-called "tanks," used with such effectiveness by the British army in the European War, were nothing more than armored Stockton "caterpillar" tractors. Notable among Stockton manufactures is the bean threshing machine that performs every operation from threshing to recleaning the beans. Stockton contains the only window glass factory west of the Mississippi. Dredges and ditch digging machinery, which have played so important a part in the reclamation and irrigation of the San Joaquin delta, are manufactured in Stockton. Stockton contains one of the four electrical steel furnaces west of Chicago. Machine works and foundries supply machinery and castings throughout the Pacific

Coast. A large cannery uses a substantial part of the output of the numerous orchards and truck gardens near the city. Other important manufactures are sole, harness and other leathers, paper, scoured wool, boats and barges of varied descriptions, paving machinery, common and fire brick, engines (marine, gas, gasoline, distillate and crude oil), ice, beer, wine, brandy, olive oil, butter, insect powder (Buhach), macaroni, pumps, windmills, wagons, gloves, soap, paint, jewelry, soda water, medicines, cigars and bread and candy for a large territory.

Municipal Facilities.—Stockton is an attractive, modern city, having 12 public parks, including one of 27 acres at the northwest corner of the city, a good electric car system, and 190 miles of streets of which 32 miles are paved with asphalt and 53 miles with miscellaneous pavements, principally asphalt bound macadam. There are in Stockton two large public baths supplied by warm artesian water, a park with picnic grounds and a baseball diamond. Stockton Channel, the San Joaquin River and Lake Yosemite also afford opportunities for swimming as well as rowing and other water sports. Stockton is one of the best shaded cities in California, the most popular trees along the streets and in the gardens being the elm, the maple, the acacia, the orange, the palm, the oleander and the umbrella tree. From 27 wells, varying in diameter from 12 to 20 inches, and in depth from 250 to 1,100 feet, water is pumped direct into the city mains, against a head of 110 feet above the ground level, using a 200,000 gallon steel tank at that elevation for balancing. These 27 wells are located at three separate stations about two miles apart. Twenty of them are located on a 10-acre tract and supply from 8,000,000 to 10,000,000 gallons daily, without showing any diminution of their capacity. The water system is owned by a private corporation. Rates are regulated by the Railroad Commission of California.

The city has a fully-paid and well-equipped fire department with 38 men. The police department has 36 men. A post-office of the first class, has an annual revenue of about \$150,000, 65 employees and 7 rural delivery routes, one of which, serving the delta, is a water route, of which there are only three or four in the United States, delivery being made by launch. There are about 7,500 telephones connecting at Stockton, including 265 reaching nearby farming districts; 36 church organizations and 26 buildings used for religious purposes; 15 public schools valued at \$752,600 and enrolling about 4,200 pupils, the high school group of buildings, including the science, manual arts and gymnasium buildings, costing \$206,000; 2 parish schools, including Saint Agnes College; a business college, a normal school and a number of smaller private schools and academies. The public library cost \$75,000 and has 70,000 volumes and 33,000 pamphlets, maps and atlases. It serves not only the people of Stockton but 26 deposit stations throughout San Joaquin County. There are 17 hotels, including the half-million dollar Mission hotel facing the plaza, built by the people of Stockton; the buildings of the State Hospital for the Insane; Saint Joseph's Home and Hospital; Young Men's Christian Association building; Elks' building; several bank

buildings, the 10th story and roof of one of which is occupied by the chamber of commerce; three daily papers, one semi-weekly and five weekly papers are published in the city. The eight banks of Stockton have a paid-up capital of \$2,802,700, with surplus, undivided and other profits of over \$1,821,000; deposits amounting to over \$20,661,000, including the circulating notes of national banks; loans over \$17,644,000; and resources aggregating in excess of \$25,285,000. There are three building and loan associations with assets of over \$1,882,000. The assessed valuation of all property in the city proper is about \$29,000,000; bonded indebtedness, \$750,000.

History and Government.—In 1843, Capt. C. M. Weber, the founder of Stockton, secured a grant of 11 square leagues (48,747 acres) of land from the Mexican government. This grant known as the Campo de los Franceses included the site of the present city of Stockton. At first stock raising was the only industry. With the discovery of gold in 1848, Stockton became at once the most important supply station for the southern mines. At the head of navigation on the San Joaquin River, goods were brought on sailing vessels from San Francisco to Stockton, the nearest point to the mines. From Stockton supplies were sent to the miners by ox teams, by pack animals or in huge wagons known as "prairie schooners." As grain farming developed, the city naturally became the shipping point for the entire tributary region. The completion of the first overland railroad in 1869 greatly increased the importance of Stockton as a manufacturing and distributing centre. In 1850 Stockton was incorporated with a population of 2,000. The city's growth has been steady and substantial. Under the charter of 1911 the elective officers of the city are a mayor, four councilmen and 5 school directors, so classified that their terms do not expire coincidentally. They serve for four years. The council designates one councilman to be commissioner of finance, revenue and public supplies, who shall be ex-officio treasurer, one to be commissioner of public health and safety, one to be commissioner of public works and one to be commissioner of audit. The city was named in honor of Commodore Robert Field Stockton of the United States navy. It was laid out in blocks 303 feet square.

Population.—(1890) 14,424; (1901) 17,506; (1910) 23,253. A complete census of the city is taken each year by the school census marshals. In 1914 well-developed territory to the north, east and south was incorporated within the city limits. The population of the city and its immediate tributary territory is estimated at 52,219.

STOCKTON-ON-TEES, tēz, a seaport town in Durham, England, situated on the Tees River, 11 miles northeast of Darlington. The river is navigable for vessels of heavy draught. Stockton consists of two sections, the town proper and South Stockton of more recent date, connected by a fine modern bridge. It has municipal buildings, a custom-house, many good churches, quays and steam tramways. There is a fine race-course in the vicinity and Ropner Park, laid out in 1893. Shipbuilding is an extensive industry and there are important foundries, blast-furnaces, engine-works and pot-

teries, breweries, corn and spinning-mills and factories for the making of sail cloth, ropes and linen. The exports include iron-ware and pottery; the imports are chiefly corn, timber, etc. There is quite a brisk river trade. The *Stockton* and *Darlington* were the first boats to carry passengers and goods. Pop. about 52,000.

STODDARD, stōd'ard, Amos, American soldier: b. Woodbury, Conn., 26 Oct. 1762; d. Fort Meigs, Ohio, 11 May 1813. He served in the Revolutionary War and at its close practised law in Maine. He was governor of the Territory of Missouri, 1804-05, fought in the War of 1812 and was mortally wounded in the siege of Fort Meigs. He published 'Sketches of Louisiana' (1810), and several valuable historical papers.

STODDARD, Charles Augustus, American Presbyterian clergyman: b. Boston, 28 May 1833. He was graduated from Williams College in 1854; taught; traveled in Europe and the East; studied at the University of Edinburgh and the Free Church of Scotland Theological Seminary, and was graduated D.D., from Williams College 1871; Union Theological Seminary in New York in 1859. He was pastor in a Presbyterian church in New York, 1859-83; became associate editor of *The Observer* in 1869, part owner in 1872 and was owner and editor-in-chief, 1885-1902. His publications include 'Across Russia from the Baltic to the Danube' (1891); 'Glimpses of Gibraltar and Tangier' (1892); 'A Spring Journey to California' (1895); 'The Centennial Celebration of Williams College.'

STODDARD, Charles Warren, American author: b. Rochester, N. Y., 7 Aug. 1843; d. 24 April 1909. He studied at the University of California and was for some time an actor and for seven years special traveling correspondent of the *San Francisco Chronicle*, visiting nearly every quarter of the globe and spending five years in the South Seas. From 1885 to 1887 he was professor of English literature at Notre Dame College, Indiana, and from 1889-1903 at the Catholic University of America. Among his publications are 'Poems' (1867); 'South Sea Idylls' (1873); 'Summer Cruising in the South Seas' (1874); 'Mashallah' (1880); 'The Lepers of Molokai' (1885); 'A Troubled Heart' (1885); 'Hawaiian Life'; 'Lazy Letters from Low Latitudes' (1894); 'The Wonder-workers of Padua' (1896); 'A Cruise under the Crescent' (1898); 'Over the Rocky Mountains to Alaska' (1899); 'Hither and Yon'; 'In the Footprints of the Padres' (1902); 'Exits and Entrances' (1903); 'The Island of Tranquil Delights' (1904). Consult James, G. W., 'Charles Warren Stoddard' (in 'Apostrophe to a Skylark,' Los Angeles 1909).

STODDARD, Elizabeth Drew Barstow, American poet and novelist: b. Mattapoisett, Mass., 6 May 1823; d. New York 1902. She was married to R. H. Stoddard (q.v.) and frequently collaborated with him in literary work. In addition to verse of not a little individuality she wrote three novels, 'The Morgesons' (1862); 'Two Men' (1865), and 'Temple House' (1867), which display vigor and originality. Her 'Poems' were collected in 1867.

STODDARD, Francis Hovey, American educator and writer: b. Middlebury, Vt., 25 April 1847, son of Solomon Stoddard, professor of languages in Middlebury College. He was graduated from Amherst College in 1869; studied for two years at Oxford, England; received the degree of M.A., from Amherst College in 1886, of Ph.D., from Western University of Pennsylvania in 1896 and of LL.D., from New York University in 1914. He was instructor in English at the University of California from 1886 to 1888 and professor of English language and literature at New York University from 1888 to 1914. From 1910 to 1914 he was dean of the College of Arts at New York University. He retired in 1914. He has published 'The Modern Novel' (1883); 'The Ideal in Literature' (1884); 'Psycho-biography' (1885); 'Women in the English Universities' (1886); 'The Cædemon Poems' (1887); 'Conditions of Labor in England' (1887); 'Miracle Plays and Mysteries' (1887); 'Tolstoi and Matthew Arnold' (1888); 'The Uses of Rhetoric' (1888); 'Inductive Work in College Classes' (1889); 'Literary Spirit in the Colleges' (1893); 'Lord Byron' (introduction to works, 1899); 'The Evolution of the English Novel' (1900); 'The Life of Charles Butler' (1903); 'Poems of National Spirit' (edited with introduction, 1904).

STODDARD, John Lawson, American lecturer and traveler: b. Brookline, Mass., 24 April 1850. He was graduated from Williams College, 1871 and studied divinity at Yale. He has traveled extensively and is the originator and promoter of the Stoddard Lectures in the larger cities of America. He has made his home in Italy for years. He has published 'Red Letter Days Abroad' (1884); 'Glimpses of the World' (1892); 'Stoddard Lectures on Travels Abroad and in America' (1898-1909); 'The Stoddard Library' (1910); 'Poems' (1911); 'Poems on Lake Como' (1914).

STODDARD, John Tappan, American educator: b. Northampton, Mass., 20 Oct. 1852. Prepared for college in the Northampton High School and after a year's experience in the wholesale woolen business in Boston entered Amherst College, graduated in 1874. Assistant principal of Northampton High School, 1874-75, graduate student in chemistry and physics at Amherst, 1875-76; University of Göttingen, 1876-77; received degree of A.M., and Ph.D., from Göttingen in November 1877. After two months in Paris he returned to Northampton and became a member of the faculty of Smith College, professor of physics and mathematics, 1878-81, of chemistry and physics, 1881-97, of chemistry, 1897. In 1886 he devised a practical method for making composite photographs (suggested by Francis Galton) and made many composites, especially of college classes, publishing two illustrated articles on composite photography in the *Century* magazine (March and November 1887). He invented the universally used wire-test tube holder (1889), a balance for first year's work and numerous other laboratory devices. Author of 'Outline of Qualitative Analysis' (1883), which has been widely used; 'Lecture Notes on General Chemistry' (1884-85, 2 vols.); 'Quantitative Experiments in General Chemistry' (1908); 'Introduction to General Chemistry' (1910); 'The

Science of Billiards' (1913); 'Introduction to Organic Chemistry' (1914); 'Photography' in 'Johnson's Universal Cyclopedia' (1905), besides many scientific articles and reviews.

STODDARD, Richard Henry, American poet and journalist: b. Hingham, Mass., 2 July 1825; d. New York 12 May 1903. He went to New York when very young and there he was employed for some time in an iron-foundry. He began, about 1848, to write in prose and verse for periodicals and ultimately devoted himself to literature. From 1853 to 1870 he was connected with the custom-house, in 1870-73 he was secretary to General McClellan, in 1860-70 was literary reviewer for the *World* and from 1880 for the *Mail and Express* (now the *Evening Mail*). The amount of his critical work in these posts was very large. He wrote much worthy verse, lyric and narrative, of a reflective cast patterned in the earlier period after Keats. 'Abraham Lincoln,' an ode, is among his best efforts. Among his numerous writings are 'Footprints' (1849); 'Songs of Summer' (1856); 'The King's Bell' (1862); 'The Children of the Wood' (poems, 1867); 'Putnam the Brave' (1869); 'The Book of the East' (1871); 'Mémorial of E. A. Poe' (1875); 'Poems' (1880, collected); 'Life of Washington Irving' (1886); 'The Lion's Cub' (1890), poems; and 'Under the Evening Lamp' (1893), essays on Hogg, David Gray, Ebenezer Elliot, Edward Fitzgerald and others. His valuable collection of autographs and manuscripts was presented by him to the New York Authors' Club, a few months before his death. Consult his 'Recollections, Personal and Literary,' edited by Ripley Hitchcock, with introduction by E. C. Stedman (1903).

STODDARD, William Osborne, American author and journalist: b. Homer, N. Y., 24 Sept. 1835. He was graduated at the University of Rochester in 1857, tried farming and journalism until 1861, when he was three months in the United States volunteers. He was secretary to President Lincoln, 1861-64 and United States marshal of Arkansas, 1864-66. Afterward he followed journalism and business pursuits in New York and took out nine patents for inventions. His publications are numerous and comprise verse, biography, fiction and adventure stories for boys. Among them are 'Scanderoon' (1870); 'Life of Abraham Lincoln' (1884); 'The Talking Leaves' (1885); 'The Red Mustang' (1890); 'Table Talk of Lincoln' (1892); 'The Lost Gold of the Montezumas' (1897); 'The Errand Boy of Andrew Jackson' (1902); 'The Boy Lincoln' (1905); 'Dan Monroe' (1905); 'Two Cadets with Washington' (1906); 'In the Open' (1908); 'Dab Kinzer' (1909); 'The Captain of the Cat's-Paw' (1914).

STODDERT, stöd'ért, Benjamin, American Revolutionary soldier and statesman: b. Charles County, Md., 1751; d. Bladensburg, Md., 18 Dec. 1813. He was educated for mercantile pursuits, but on the outbreak of the Revolutionary War entered the Continental army and served with distinction until the battle of Brandywine, when he was severely wounded and obliged to retire from active service. At the time of his retirement he had the rank of major. He was Secretary of the Board of War till 1781. At the close of the war he estab-

lished a mercantile business at Georgetown, D. C. In 1798 he was appointed Secretary of the Navy, holding the position till 1801. During his administration, war with France was threatened and he had charge of the organization of the naval force. For a time he served also as Secretary of War. At the close of his term he returned to business in Georgetown.

STOECKEL, Gustave Jacob, American musician and instructor: b. Maikammer, Germany, 9 Nov. 1819; d. Norfolk, Conn., 17 May 1907. He graduated from Kaiserslautern, Germany, and for several years was a teacher and organist. He came to the United States in 1847, becoming instructor in music at Yale University in 1849 and the organist in College Chapel. After 1890 he was professor emeritus of music. He published several collections of sacred music, several operas and College Hymn Book for male voices.

STOESSEL, Anatoli Mikhailovitch, Russian general: b. of Swedish parents in Saint Petersburg, 10 July 1848; d. 1915. He was educated in Paul Military School, Saint Petersburg, and entered the army in 1864, serving with distinction in the Russo-Turkish War, 1877-78. He was appointed colonel in 1889, major-general in 1899, commander of the Ninth East Siberian Sharpshooters' Brigade, 1900, and for meritorious services against the Boxers in the same year, was made a lieutenant-general. At the outbreak of the Japanese War in February 1904, he was appointed commander at Port Arthur, and soon afterward commander of the entire army corps ordered to the defense of that fortress, which he surrendered to the Japanese, 2 Jan. 1905. On 20 Feb. 1908 he was condemned to death (commuted to 10 years' imprisonment) "for surrendering the fortress before all means of defense had been exhausted; failing to enforce authority; and for military misdemeanors." A year later he was pardoned.

STOEVER, Martin Luther, American educator and author: b. Germantown, Pa., 17 Feb. 1820; d. Gettysburg, Pa., 22 July 1870. He graduated from Pennsylvania College, Gettysburg, in 1838, and was a tutor there from 1839 to 1840, afterward becoming principal of the preparatory department and professor of Latin, history and political economy, a position which he very ably held until his death. For several years he acted as secretary of the General Synod of the Lutheran Church, and as editor of the *Evangelical Quarterly Review*, for which he wrote a series of 'Reminiscences of Lutheran Ministers.' He also edited 'The Literary Record' from 1847 to 1848. He published biographies of Dr. Henry M. Muhlenberg (1856), and of Dr. Philip F. Mayer (1859), and wrote 'A Brief Sketch of the Lutheran Church in the United States' (1860). At the time of his death was preparing a full history on that subject.

STOHMANN, stō'man, Frederick Karl Adolf, German agricultural chemist: b. Bremen, 1832; d. 1897. He was educated at Göttingen University, Germany and London; was assistant professor under Graham at University College from 1853 to 1855, and afterward assistant at Celle. He organized the department for agricultural experiments at Brunswick in 1862;

in 1865 he accepted a call to Halle, and in 1871 became director of the agricultural physiological institute of Leipzig University. He wrote 'Beiträge zur Begründung einer rationellen Fütterung der Wiederkäuer' (1860); 'Biologische Studien' (1873); 'Handbuch der technischen Chemie' (1872); 'Handbuch der Zuckerfabrikation' (1878); 'Die Stärkefabrikation' (1878); 'Die Milch-und Molkereiprodukte' (1898).

STOICISM, the Stoic system of philosophy and practical attitude toward life. The Stoic school of philosophy was founded at Athens, about 300 B.C. by Zeno, a native of Citium, in Cyprus. It received its name from the Stoa Poecile, or mottled porch, where its meetings were held. Zeno had been a pupil of the Cynic Crates, and in its essential principle Stoicism may be regarded as the continuation and scientific development of Cynicism (q.v.). The successor of Zeno in the leadership of the school was Cleanthes, the author of the hymn to Zeus, who died 251 B.C. He was followed by Chrysippus who, on account of his great activity as a teacher and writer, is sometimes called the second founder of the school. The leadership, at Athens then passed the order to Zeno of Tarsus, Diogenes of Seleucia and Antipater of Tarsus. Of the numerous writings of these men and their contemporaries only a few fragments have come down to us.

Panætius of Rhodes (180-110 B.C.) and his contemporary, Boethius of Sidon, introduced new elements into Stoicism, bringing it into closer relations with the systems of Plato and Aristotle. It was mainly through the influence of the former that Stoicism was introduced into Rome. Panætius was the friend of Scipio Africanus and of Lælius, and the teacher in philosophy of many Roman youths of distinguished families. Cato, the younger, is perhaps the most famous Roman Stoic of the time of the republic. By the time of the empire, the original form of Stoicism had been greatly modified by the prevailing eclecticism of the age, and may almost be said to have ceased to exist as a scientific system. It still survived, however, as a popular moral philosophy, and in this form gave expression to many of the noblest ethical and religious convictions of the ancient world. Its chief representatives at this time whose works are still extant were Seneca, Epictetus and the Emperor Marcus Aurelius.

Stoicism, like all the later systems of Greek thought, was primarily practical in character. The end and object of philosophy for the stoic was to teach virtue as the art of right living. But, in order to act rightly, it is necessary to be able to reason correctly and to understand the nature of the universe of which man is a part. Hence, logic and physics were regarded as indispensable preliminary studies for ethics, but not as possessing an independent value of their own. The extensive logical investigations undertaken by the Stoics contributed little of permanent value for the development of the science. In physics, their general view of the universe may be described as pantheistic materialism. Whatever exists is for the Stoics a material body. Not only do they maintain that all substances—including the soul and God—are corporeal, but they go on to describe as material all properties and relations

of things, and even virtues and vices. Their view of the world was, however, essentially dynamic: all is process and movement. Moreover, the world-process forms a single whole, whose unitary principle is sometimes described in material terms, similar to those of Heraclitus (q.v.), as fire of warm breath, sometimes in spiritual terms as God, Providence, the Logos or Universal Reason, or Universal Law. In spite of the variety of terms, these names all have for the Stoics the same meaning, and describe at once both the essential substances of the world, and the ordering power and principle according to which it is regulated. There is no distinction to be made between God and the world, between matter and force. Further, these statements imply that every part of the world is ruled by the same unchanging laws, and is thus subjected to strict necessity. There is no chance or contingency anywhere; everything is ruled and governed by unvarying laws.

Man only differs from the other parts of the universe in that, as possessing consciousness and reason, he is able to learn the laws of nature and to follow them consciously and voluntarily. Hence we find that the fundamental doctrine of the Stoic ethics is contained in the injunction to "follow nature," to lead a "life according to nature." This general principle was made more specific, however, when it was pointed out (it is said by Chrysippus) that the laws of nature with which man is most directly and intimately concerned are those of human nature, and that he must therefore obey the fundamental laws which are found within himself. This implies that reason, the fundamental principle of human nature, shall govern action. Between the reason and the life of feeling and emotion there is the sharpest opposition. The highest good is not pleasure, or any object of desire, but virtue, the end which reason shows to be in harmony with our true nature. This sharp antithesis between virtue and pleasure was doubtless made more emphatic by the rivalry between the Stoic and the Epicurean schools. To regard pleasure as the good is, they maintain, to lose sight of the true nature of virtue, to base it upon the feelings and emotions, which are subject to external circumstances, and thus to deprive a man of his moral freedom and independence. The ideal of the wise man plays a very important part in the Stoic ethics. The wise man is completely free and independent, completely independent of external circumstances, and entirely emancipated from the bondage of the desires and emotions. For him virtue is the only good and vice the only evil: all external circumstances are indifferent; health, power, riches, even life itself are not real goods, nor is pain, poverty, contempt, or death evils. He has completely mastered his possessions through the insight of reason and the resulting strength of will, and has attained to a state of apathy, or freedom from the sway of the emotions. This ideal has been realized at best by very few men; the Stoics refer only to Socrates and Antisthenes, the founder of the Cynic school, as examples of its complete fulfilment. The wise man recognizes the necessity of all events, and welcomes whatever takes place as a part of the divine order of the universe.

The fundamental Stoic virtues are thus strength of will and resignation based on rational insight. These enable a man to bear cheerfully whatever lot fortune may apportion to him. Even when external circumstances make endurance no longer possible, but would compel a man to unworthy action, he may still triumph by voluntarily withdrawing from life by suicide. The Stoic gives up life, as he gives up external goods, as a means of preserving his own freedom and independence; and many of the most famous members of the school committed suicide in this spirit. In spite of the emphasis on the necessity of independence, the Stoics recognize that a life of reason implies social relations with one's fellow-men, and they give an important place in their system to the social duties and virtues, especially to the importance of justice, mercy and friendship. As reason is the essential basis of society, being the common element that unites a man with his fellows, they attach slight importance to citizenship in a particular country, and emphasize the cosmopolitan idea of social unity with all rational beings of every society and of every country. In this and in other doctrines, Stoicism, especially in its later form, goes beyond the conceptions usually prevailing in Greek ethics, and approaches the Christian idea of the universal brotherhood of man.

Bibliography.—Seneca, 'Dialogues' (tran. by A. Stewart in Bohn Library); Epictetus, 'Discourses and Encheiridion' (tran. by G. Long in Bohn Library); Aurelius, Marcus, 'Thoughts' (tran. by G. Long in Bohn Library); Capes, 'Stoicism' (1880); Zeller, E., 'Stoics, Epicureans and Sceptics' (tran. from Ger. by O. K. Reichel, 1892); Brown, J. B., 'Stoics and Saints' (1893); Davis, 'Greek and Roman Stoicism' (1903); Bevan, E. R., 'Stoics and Sceptics' (Oxford 1913).

JAMES E. CREIGHTON,
Professor of Philosophy, Cornell University.

STOJOWSKI, Sigismund, American pianist and composer: b. Strelzy, Poland, 1870. He studied under Zelenski in Cracow, and under Diémer, Paderewski, Dubois and Massenet in Paris. He toured Europe successfully as a pianist, and in 1906 became professor of piano-forte at the Institute of Musical Art, New York. Since 1913 he has been professor of piano-forte at the Von Lnde School of Music, New York. Author of 'Symphony in D Minor'; several violin sonatas and piano concertos; 'Romanza' for violin and orchestra; 'Der Frühling,' a choral work with orchestra; and many pieces for the piano and the violin.

STOKE NEWINGTON, a metropolitan borough of London, bounded east by Hackney and west by Islington. Area, 863 acres. Pop. 50,659.

STOKE-POGES, stōk pō'jīs, England, a village of Buckinghamshire. It is the burial place of Thomas Gray, and its churchyard is the scene of the famous 'Elegy.'

STOKE-UPON-TRENT, England, a seaport and market-town, in Staffordshire, 14 miles northwest of Stafford, capital of the "Potteries" district. It dates mainly from the 18th century and has been greatly improved recently. The municipal buildings, free library, Minton Me-

morial, Hartshill infirmary, monuments to prominent citizens and public baths are noteworthy features. The industries and manufactures are varied, including earthenware, porcelain, tiles, tessellated floors or pavements, coal-mining, the manufacture of machinery, engines, etc. Pop. about 30,458.

STOKER, Bram (Abraham), English author: b. Dublin, 1848; d. 22 April 1912. He was educated at Dublin University. He entered the government civil service and while there he became noted as a literary, art and dramatic critic on various Dublin newspapers. In 1876 he was associated with Henry Irving in the management of the Lyceum Theatre and has published 'Under the Sunset' (1882); 'The Snakes' Pass' (1891) 'The Watter's Mou' (1894); 'The Shoulder of Shasta' (1895); 'Dracula' (1897); 'Miss Betty' (1898); 'The Mystery of the Sea' (1902); 'The Jewel of Seven Stars' (1903); 'The Man' (1905); 'Personal Reminiscences of Henry Irving' (1906); 'Lady Athlyne' (1908); 'Snowbound' (1909); 'The Lady of the Shroud' (1910).

STOKER, Sir (William) Thornley, Irish surgeon: b. 6 March 1845; d. 3 June 1912. He obtained his early education in the Wymondham Grammar School, later studying in the College of Surgeons, Ireland, and Queen's College, Galway. He rapidly attained eminence in his practice and was created a knight in 1895 in recognition of his services to surgery. He was appointed surgeon to the City of Dublin Hospital in 1873; appointed surgeon to Richmond Hospital 1873, and Swift's Hospital 1876, later becoming governor. He was professor of anatomy in the Royal College of Surgeons, Ireland, 1876-89, and its president, 1894-96; governor of the Royal Hibernian Military School, the House of Industry Hospitals and of the National Gallery, Ireland; he was appointed inspector for Ireland, under the Vivisection Act and was a Fellow of Royal University from 1890. He contributed many scientific papers on his profession to magazines and periodicals.

STOKES, Adrian, English painter: b. Southport, in 1854. He received his education at the Liverpool Institute and the Royal Academy Schools, London. He has exhibited works at the Royal Academy each year since 1876 and has been awarded medals at the Paris Exhibition, 1889, and the World's Fair at Chicago, 1893. He has also written much on art for magazines and newspapers.

STOKES, Anson Phelps, American financier and reformer, father of J. G. P. Stokes and A. P. Stokes (qq.v.): b. New York, 22 Feb. 1838; d. 28 June 1913. He was early engaged in the mercantile business, later was a member of the banking firm, Phelps, Stokes and Company, and was prominent in financial circles. He was the first president of the Reform Club, New York; was vice-president of the Civil Service Reform Association, and was president of the National Association of Anti-Imperialist clubs. He was deeply interested in social reforms and was prominent in works of charity, to which he contributed liberally. Author of 'Joint-Metallism' (1894; 5th ed., 1896); 'Cruising in the West Indies' (1902); 'Cruising in the Caribbean with a Camera' (1903).

STOKES, Anson Phelps, American Protestant Episcopal clergyman and educational writer, son of A. P. Stokes (q.v.): b. New Brighton, S. I., 13 April 1874. He was graduated at Yale University in 1896 and at the Episcopal Theological Seminary, Cambridge, in 1900. He traveled in China, Japan, India and other countries in 1896-97; has been secretary of Yale University since 1899, and minister of Saint Paul's Church, New Haven, since 1900. He is also secretary of the Phelps Stokes Foundation for educational work among negroes; and since 1912 has been a member of the General Education Board. Author of 'Memorials of Eminent Yale Men' (1914); 'What Jesus Christ Thought of Himself' (1916); 'Historic Universities in a Democracy' (1913); 'The Question of Preparedness' (1916).

STOKES, Frank Wilbert, American artist; b. Nashville, Tenn. He was educated at Philadelphia, Pa.; studied music under Prof. Hugh Clark of the University of Pennsylvania, and art under Eakins, at Philadelphia Academy of Fine Arts. In Paris he studied art under Gérôme at École des Beaux Arts; also at Colonn's under Raphael Collin and Academy Julien under Boulanger and Lefevre. He lived four years at Etampes, Pas-du-Calais; exhibited at Salon Société des Artistes Français for four years; returned to United States in 1891; in 1892 accompanied Peary Relief Expedition for *Scribners Magazine*; in 1893 was artist member of Peary's North Greenland Expedition, 17 months in Bowdoin Bay, Greenland, building a studio and painting from natives and nature. Remained in Philadelphia until 1900 then going to New York City in 1901 joined the Swedish Antarctic Expedition under Dr. Otto Nordenskjoeld, at Buenos Aires, Argentine, remained about eight and one-half months painting from nature as member of the 'Land Party.' The expedition failed in landing on the Antarctic continent and Mr. Stokes left the expedition at Port Stanley, Falkland Islands, and thence by steamer to Montevideo, Uruguay, Buenos Aires and finally via Antwerp returned to the United States. Mr. Stokes paid his way with all of the above expeditions, in order to be independent and do his special work. Lectured and exhibited at various places in the United States and Canada, London, England, and exhibited paintings at Salon of Société Nationale des Beaux Arts; lectured before Société de Géographie de Paris, also before Società Geografica Italiana, Rome, Italy, before the king and queen. Awarded Prix Alphonse de Montyot silver medal by the Société de Géographie de Paris. Painted and completed in 1909 a series of mural decorations for Eskimo Hall of the American Museum of Natural History of New York, on legends and the life of the Eskimo. His publications include essays in 'Color in Far North' (1894); 'An Arctic Studio' (1896); 'Essentials of Polar Expedition' (1900), in *Philadelphia Saturday Evening Post*; 'Aurora Borealis'; 'An Art in the Antarctic' and 'In the Tropics' (in *Century Magazine* 1903); 'Color in Polar Worlds' (1906), International Geographical Congress.

STOKES, Frederick Abbott, American publisher: b. Brooklyn, N. Y., 4 Nov. 1857. He was graduated at Yale University in 1879 and in 1881 established a publishing house known as

White and Stokes. The firm became White, Stokes and Allen in 1883; Frederick A. Stokes in 1887; Frederick A. Stokes and Brother in 1888; and since 1890 has been Frederick A. Stokes Company, Mr. Stokes being its president. He edited 'Poems of Sir John Suckling' (1886); and the *Pocket Magazine* in 1898-1901; and has contributed to various magazines.

STOKES, Sir George Gabriel, British mathematician and physicist: b. Skreen, County Sligo, Ireland, 13 Aug. 1819; d. 1903. He was graduated at Cambridge in 1841, in the same year was elected a Fellow of Pembroke College and was elected Lucasian professor of mathematics at Cambridge in 1849. In 1885 he became president of the Royal Society and from 1887 to 1892 was member of Parliament for Cambridge University. He was made a baronet in 1889 and in 1902 became master of Pembroke College. He was distinguished as an expounder of the principles of hydrodynamics and of the phenomena of fluorescence and phosphorescence and he was the first to demonstrate in college and public lectures the scientific principles of spectrum analysis. He greatly extended the field of physical inquiry and demonstrated more clearly than had ever before been done the relation of physics and the natural sciences in general to higher mathematics. He was also a high authority on optics. His work, especially in mathematical physics, was brilliant and exact. He attempted successfully the solution of problems thought by leading scientists to be practically unsolvable. His publications include the 'Burnet Lectures on Light' (1892); 'Mathematical and Physical Papers' (1880-1902); 'Gifford Lectures on Natural Theology' (1891-93), and more than 100 important papers printed in the transactions of learned societies. His mathematical and physical papers were collected and published in five volumes at Cambridge (1880, 1883, 1901, 1904 and 1905), and his 'Memoir and Scientific Correspondence,' also at Cambridge in 1907. Consult Brown, E. W., 'Biography of Stokes' (in 'Annual Report of Smithsonian Institution, 1904,' Washington 1905).

STOKES, Henry Newlin, American chemist: b. Moorestown, N. J., 24 Oct. 1859. He was graduated at Haverford College (1878) and received the degree of Ph.D., at Johns Hopkins (1884), whence he went to Europe. From 1884-89 he studied at the University of Munich and Federal Polytechnic, Zurich, Switzerland. He was chemist for the United States Geological Survey 1889-92 and 1894-1903, becoming assistant professor of inorganic chemistry (1892-93) and associate chemist, Bureau of Standards (1903-09).

STOKES, James Graham Phelps, American Socialist: b. New York, 18 March 1872. He was son of Anson Phelps Stokes and was graduated (1892) at Sheffield Scientific School (Yale). In 1896 he received the degree M.D., at the College of Physicians and Surgeons (Columbia), when he took up graduate work in the School of Political Science, Columbia (1896-97). In 1905 he married Rose Harriet Pastor, prominent Socialist leader and lecturer. He spent much time on the governing boards of the corporations in which his family estate was interested. In very numerous philanthropic institutions, such as the New York Association

for Improving the Condition of the Poor, University Settlement Society, Federation of Christian Churches and Christian Workers, Peoples' Institute, Tuskegee Normal and Industrial Institute, etc., he has done much practical work. From 1906 he has devoted his activities largely to the Socialist cause, being president of the Intercollegiate Socialist Society (1907-17), presidential elector on Populist ticket (1904), vice-chairman, Municipal Ownership League, its candidate for president of board of aldermen, New York (1905). In 1911 he was member of the State executive committee of the Socialist party of Connecticut; candidate for New York assembly (1908); candidate for mayor of Stamford, Conn. (1912). In 1917 he withdrew from the Socialist party, together with numerous other leaders when the party views were pacifist and antagonistic to the American government and its war policy. In the latter year he became vice-chairman of the Nationalist party, secretary-treasurer of the Social Democratic League of America, etc. He enlisted (1917) in the Veteran Corps of Artillery, New York, and was transferred to Ninth Coast Artillery, New York.

STOKES, Whitley, Irish Celtic scholar: b. Dublin, 28 Feb. 1830; d. 1909. He was educated at Trinity College, Dublin, and called to the bar at the Inner Temple in 1855. He went to India in 1862 and became successively secretary to the governor-general's legislative council and to the legislative department of the government of India. In 1877-82 he was law member of the governor-general's council and during his official career in India drafted the greater part of the present Anglo-Indian codes of civil and criminal procedure (4 vols., 1887-91) and numerous acts relating to property, trusts, etc. In 1879 he was president of the Indian Law Commission. In 1868 he proposed a scheme for collecting and cataloging the Sanskrit manuscript preserved in India. His published works include those treating of legal and those dealing with Celtic subjects, by the latter of which he is best known to the literary and scientific world. He began his Celtic studies in his youth and continued them enthusiastically all his life. Most of his work is of a very learned nature, and some of it is of high literary merit. Especially faithful and sympathetic are his translations from Celtic into English. His Celtic studies and writings include Irish, Scotch, Welsh, Breton and Cornish. He has placed, through his researches, a vast amount of early Celtic material at the disposition of students of the Celtic tongues. The former comprise 'Treatise on the Liens of Legal Practitioners' (1860); 'On Powers of Attorney' (1861); 'Hindu Law Books' (1865); 'The Older Statutes in Force in India, with Notes' (1874); and 'The Anglo-Indian Codes' (1887-8; supplements, 1889-91) etc. Among his Celtic works may be named 'Irish Glosses' (1860); 'Three Irish Glossaries' (1862); 'The Play of the Sacrament' (1862); 'The Passion, a Middle Cornish Poem' (1862); 'The Creation of the World, a Cornish Mystery' (1863); 'Three Middle Irish Families' (1871); 'Goidelica' (1872); 'The Life of Saint Meriasek' (1872); 'Middle-Breton Hours' (1876); 'The Calendar of Aengus' (1880); 'Tripartite Life of Saint Patrick' (1887, in the Rolls Series); 'Lives of Saints from the Book of Lismore'

(1889); 'Urkeltischer Sprachschatz' (1894), with Bezzenberger; 'The Martyrology of O. Gorman' (1895); 'The Annals of Tigernach' (1897); 'The Eulogy of Saint Columba' (1899). He is joint-editor of 'Irische Texte' and of the 'Archiv für Celtische Lexikographie.'

STOKOWSKY, stō-kōf'ski, **Leopold**, American orchestral conductor: b. London, Eng., 1882. He was graduated at Queen's College, Oxford, studied instrumentation at Paris and came to New York in 1905. He conducted symphony, operatic and oratorio work in Paris, and was musical director (1905-08) of the New York Saint Bartholomew's choir. From 1909-12 he was conductor of the Cincinnati Orchestra, and (since 1912) of the Philadelphia Orchestra.

STOLA, the Latin name of a loose garment worn by Roman matrons over the tunic. To the bottom of it a border or flounce was sewed, the whole reaching down so low as to conceal the ankles and part of the feet. It was the characteristic dress of the Roman matrons, as the toga was of the men. Divorced women or courtesans were not allowed to wear it. It was usually gathered and confined at the waist by a girdle, and frequently ornamented at the throat by a colored border. It had either short or long sleeves and was fastened over the shoulder by a fibula.

STOLBERG, stōl'bĕrk, **Christian**, **COUNT**, German author: b. Hamburg, 1748; d. 1821. He traveled through Switzerland and North Italy in company with Goethe and Lavater, and finally settled in Schleswig where he wrote poems and dramas. He made excellent translations into German of the Greek poet Sophocles, and other works from the Greek. His poems, which are generally of an intimate nature and depict faithfully and sympathetically family life, were published in several editions under the simple title of 'Gedichte' (1779, 1782, 1787, 1810). He was a brother of Friedrich Stolberg, and the works of the two brothers were published in 20 volumes under the general title 'Werke der Brüder Stolberg' (Hamburg 1820-25). Stolberg was influenced by Klopstock.

STOLBERG, Friedrich Leopold, **COUNT**, German poet, brother of Christian Stolberg (q.v.): b. Bramsted, 1750; d. 1819. He wrote plays, poems, travels and translated the 'Iliad,' four tragedies of Æschylus, some of the works of Plato and Ossian's poems. From 1777 to 1780 he was Ambassador to Copenhagen for Prince-Bishop of Lubeck; and Ambassador for Denmark at Berlin (1780-89). He also held other important official positions. In 1800 he and his whole family became converts to Catholicism. From this time on he lived in comparative retirement, devoting his energies to literary work. He wrote an elaborate 'History of the Religion of Jesus Christ' (15 vols., 1807-18). Consult Hennes, J. H. (Frankfort 1876); Janssen, J. (Friedburg 1900), and Menge, T. (Gotha 1862) for biographical studies.

STOLE (Latin *stola*, long robe), a long narrow band or scarf with fringed ends, worn by ecclesiastics of the Roman Catholic and Protestant Episcopal churches, by deacons over the left shoulder, being fastened under the

right arm; by bishops round the neck with both ends pendant in front to the knees; and by priests similarly, but with the ends crossed over the breast at mass.

STOLP, stölp, or **STOLPE**, stöl'p, a town in Prussia, in the province of Pomerania, on the river of its own name, 64 miles west of Dantzic. The interesting features are a castle of the 16th century, two good churches, the ancient town-gates and several schools. The industries are chiefly fishing, iron founding, linen weaving and amber turning. There is some trade in cattle, fish, geese, grain and liquor. The port is Stolpmünde at the mouth of the river. This is also a favorite summer resort. It formerly belonged to the Hanseatic League, from which it passed to Brandenburg in 1637. Pop. about 35,000.

STOLYPIN, stöl'y-pën, **Peter Arkadievitch**, Russian statesman; b. 1862; d. 1911. He studied at Saint Petersburg University, and (1885) was engaged in the 'department of public domains. He became president of the provincial court in the government of Kovno, and was promoted (1902) to governor of Grodno, and (1903) governor of Saratov. He was appointed Minister of the Interior in 1906, and then constitutional Premier after Goremykin's Duma was dissolved. He placed most of the empire under martial law to suppress the growing elements of revolution, and he was assassinated in 1911.

STOMACH. The ancients conceived digestion (q.v.) as a process of cooking, executed by the animal heat of the body. Not until the 17th century was the idea advanced that digestion in the stomach was a chemical process largely due to ferments. In 1752 Réaumur, and in 1783 Spallanzani, established that the main factor in digestion was a secretion of the stomach, the gastric juice, which dissolved and transformed the ingested food-stuffs chemically. Previous to that time—even in the 17th century—digestion was thought to be due to a mechanical trituration of the food, Réaumur knew that the secretion of the stomach was acid, but it was not until 1834 that Prout discovered that the acidity was due to hydrochloric acid (HCl). In 1836 Schwann recognized the active ferment of the gastric juice, the pepsin.

A research work of the most far-reaching importance concerning the nature of stomach digestion was executed by the American military surgeon, William Beaumont, on the stomach of the Canadian hunter, Alexis St. Martin. After a gunshot wound had opened the organ, it healed not perfectly but, leaving a fistula permitting introspection and direct, objective study of digestion. The investigations of Beaumont constitute what may justly be designated as the most epoch-making research on the physiology of the human stomach. ('Experiments and Observations on the Gastric Juice and the Physiology of Digestion,' Plattsburg, N. Y., 1833).

The digestive processes in the intestines were first systematically studied by Claud Bernard, who discovered in 1848 that the pancreatic juice digested fats. Corvoisart in 1857 discovered the albumen-digesting power of the pancreatic juice. In 1865 the secretion of the intestinal glands was gained in a pure state by Thiry.

Valuable contributions to the physiology of digestion in the stomach and intestines have been made by J. P. Pawlow, of the Institute for Experimental Medicine, Saint Petersburg. These scholarly researches belong to the most recent acquisitions of our knowledge of the digestive tract. Still much remains to be worked out. Even at the present time the function of the bile is not completely understood, nor are the functions of the liver and pancreas satisfactorily investigated. In a brief and practical account like this, the reader seeks only well-ascertained facts and not hypotheses. What he wants to know is (1) how the stomach works under healthy conditions, what are its normal performances, and (2) how its abnormal conditions are brought about, how its diseases are manifested, and what are the best means of avoiding or curing them.

Normal Gastric Digestion.—For an understanding of the normal functions of the stomach, a brief reference to recent discoveries is indispensable. The stomach is not the main digestive organ, only one-seventh of the entire digestive process occurs in it. The remaining six-sevenths of digestion are carried on in the intestines. But it would be a grave error to assume for this reason that the stomach is not necessary for the digestive process. For so dependent is intestinal digestion upon gastric digestion that it is impossible to have a normal digestion in the intestines without a previous digestion in the stomach. It is also a mistake to assume that the intestinal digestion is normal in individuals who for surgical reasons have had to undergo the operation of the removal of the stomach as a whole or in part. None of such operated cases where the entire stomach was removed have lived over a year or six months, although they were kept under constant supervision and the most careful dietetic control.

The chemical changes which the various food-articles undergo in the stomach are of far-reaching importance for the changes which are to occur in these foods after they reach the intestines. Many of the old authors, beginning with the American physiologist, Beaumont, believe that the mechanical irritation of the foods causes the gastric secretion, but the experiments in Pawlow's laboratory have proved the fallacy of this view. In the first place, if the secretions were due to simple mechanical irritation, there is no reason why irritation with the point of a glass rod, with a feather, or with sand placed in the stomach, should not also cause the secretion. A secretion may be caused by mechanic irritation, but it is composed mainly of a liquid resembling plasma, containing mucus, and having no digestive power. The mistake of the older experimenters, according to Pawlow, grew out of the fact that they ignored the so-called *psychic secretion*, a secretion which can be set up by the mere smell or sight of food, or even by a very intense feeling of hunger. If the œsophagus of a dog be cut in the neck and its end sewed to the edges of the wound, and at the same time a gastric fistula be established, pieces of meat which are fed to the dog after healing of these fistulæ will not reach the stomach, but will fall out of the upper end of the fistula leading into the œsophagus. Nevertheless in five to six minutes after the swallowing of the food gastric juice begins to be secreted,

running from the gastric canula first in drops and afterward in a continuous stream. If the dog be offered meat without receiving it, the gastric secretion will also appear, though not so plentifully as when the dog was actually allowed to chew the meat. A further interesting fact observed in dogs so experimented on was that no secretion followed the swallowing of indigestible substances like small stones. These experiments furthermore suggested that for every kind of food a definite gastric secretion is formed of specific composition. Therefore it has been said that the stomach provides a special gastric juice to meet each dietetic requirement. It must therefore be further studied whether the mucous membrane of the stomach is capable of distinguishing between the varieties and classes of foods that come in contact with it, much as the skin recognizes mechanical, chemical, thermic and electrical stimulation.

It might be asked, "What is the object of this psychic secretion?" for Pawlow has clearly established the existence of two kinds of gastric secretion, the chemic and the psychic. This question applied to the human physiology would be the same as inquiring, "What is the object of the appetite?" The answer is, that under the influence of the psychic secretion a gastric juice is furnished which is much more effective than that which is secreted under purely chemical stimulation of the food, that is, when food is taken without any special appetite. Furthermore, under the influence of psychic secretion foods which would otherwise not stimulate the gastric mucosa to secretion become converted by the already present psychic secretion into something else which constitutes a further stimulant to the secretion of gastric juice. For instance, if a solution of albumen be administered to a dog upon which a Pawlow operation has been performed, that is, splitting off part of the stomach, with all the vessels and nerves intact, and making this second smaller stomach communicate with the abdominal wall, but not with the general cavity of the large stomach from which it is dissected (see Hemmeter's Practical Physiology) there will be no secretion from the small stomach, for albumen by itself does not excite chemical secretion. But if the psychic secretion is previously set up by some other means, before the albumen is placed in the large stomach—for instance, by waving a piece of meat before the dog's eyes—then, following the introduction of albumen, a secretion will be found in the small (artificial) stomach which is qualitatively and quantitatively greater than the psychic secretion alone, or when albumen is given alone, it is evident that, while albumen in itself does not excite secretion, the products of albumen do cause this secretion. The same is true of pieces of bread which, when placed in the large stomach through the fistula, will not promote a secretion; but if the dog is allowed to swallow the bread, secretion begins and continues for several hours. Psychic secretion therefore is a preparatory secretion, transforming substances, which otherwise would not stimulate the stomach into such forms as can accomplish this stimulation. The fact that bread will cause a secretion when chewed and swallowed and not when placed directly in the stomach through the fistula, may be interpreted (as by Pawlow

and Peter Borisoff) as proving the secretion of a gastric juice under psychic influence; but—as will be shown presently—it may be due to a special body formed in the salivary glands and reaching the blood eventually circulates through the glands of the stomach and stimulates gastric secretion.

Edkin has demonstrated that the pyloric mucosa forms a chemic substance during digestion which also stimulates gastric secretion after it has once been started by other mechanisms. Further revelations from Pawlow's laboratory disclose very important relations between the various classes of food, permitting the conclusion that they may mutually advance or interfere with the digestion of their various constituents in the gastric chyme. For instance, starch paste does not by itself promote gastric secretion, but when mixed with meat it was found to accelerate the action of the gastric juice, increasing its digestive power. Furthermore, it was demonstrated that the stomach is capable of distinguishing between lactic, butyric and hydrochloric acids and responded to each of these acids with a varying quantitative secretion. As lactic and butyric acids are either contained in the food as such or are products of gastric fermentation, their stimulating influence on gastric secretion is of therapeutic importance. It is evident, therefore, not only that the stomach is extremely delicate in detecting the composition of foods and regulating the composition of its secretion correspondingly, but that it can distinguish between various organic acids. These experiments furthermore gave the clue to the treatment of gastric secretory disorders not by drugs merely but by dietetic measures.

Hemmeter found that extracts made from salivary glands that were removed from animals during the act of chewing, when injected into the general circulation of dogs caused a flow of gastric juice. This occurred when the animal's stomach was empty. All of these chemic agents that correlate the function of physiologically and anatomically distant organs are called *Hormones* by Starling (from the Greek *ὁρμῶν* (I stimulate)).

The human stomach accomplishes its work by the means of three essential functions, secretion, absorption and peristalsis (this term refers to the movements of the stomach). The secretion of the gastric glands owes its digestive power to hydrochloric acid and three ferments. The quantity of hydrochloric acid amounts to two parts in the 1,000 of gastric juice. The ferments are pepsin, which acts mainly on the proteid constituents of food like meat and egg, rennin or chymosin, which acts principally upon milk, precipitating the casein; lipase, which is a fat-digesting ferment; and the new gastric ferment, "chymaze," which is not a digestant of food, but an accelerator of the digesting action of the ferments of the pancreatic juice. (International Clinics, Vol. II, 12th Series, p. 276, article by Peter Borisoff).

Dependence of Intestinal upon Gastric Digestion.—It is a prevalent opinion among the laity that the stomach has a marked absorptive power. This is a natural consequence of an older error, according to which the stomach is the chief digestive organ, it having been formerly believed that by far the greater part of the digestive act takes place in the stomach.

As already intimated, the actual digestion which takes place in the stomach is insignificant compared with that which takes place in the intestine. Later it will be shown here that the secretion of pancreatic juice depends upon the liberation from the membrane of duodenum, or first part of the bowel, of an agent called *duodenal secretin*, another hormone (discovered by Bayliss and Starling), and that the liberation and secretion of this agent depends upon the presence of hydrochloric acid in the gastric chyme. So that if this acid is not present in the chyme as it enters the upper bowel, there can be no normal performance of intestinal digestion. Just as normal gastric digestion depends upon a normal condition of the mouth and normal salivary secretion, so normal intestinal digestion depends upon a normal stomach.

Absorption from the Stomach.—The amount of absorption that takes place from the stomach is surprisingly small. Water is practically not absorbed at all, for it appears that fully 95 to 100 per cent of all water taken into the stomach is passed out into the duodenum and absorbed from the intestine. Alcohol and substances in solution of alcohol are readily absorbed. Grape-sugar, milk, cane-sugar and maltose are absorbed in moderate amounts when they are in aqueous solution. When they are in alcoholic solution larger amounts are absorbed. Dextrin and peptones are also taken up from the stomach, but in smaller amounts than sugar. The amount of these substances absorbed increases with the concentration of the solution. But simultaneously with this absorption occurs a more or less active secretion of water into the stomach, which secretion increases or diminishes directly in proportion to the amounts of the substances absorbed. So that under certain conditions it is possible to draw more water out of the stomach by means of a stomach-tube than has been drunk half an hour previously, which certainly refutes the assumption that water could be absorbed from the stomach, and favors the view that water is not only not absorbed, but that it is actually secreted into the stomach under certain conditions. This conclusion is of great value in the treatment of certain dyspepsias characterized by a weakened condition of the gastric musculature; for in these the contractile power of the stomach is not sufficient to expel the water into the bowel in the proper time. And as water is, bulk for bulk, the heaviest substance which the human being takes into the stomach, its retention in the stomach beyond a certain length of time drags down and exhausts the already attenuated gastric muscularis and dilutes the already weakened gastric secretion. Therefore in some forms of gastric atony an essential part of the treatment consists in restricting the amount of water to the lowest possible requisite or to give it by means of colon-injections, if necessary, for a time at least; or if some of it must be taken by way of mouth, to induce the patient to lie on his right side and by means of massage to facilitate the expulsion of the water from the stomach into the intestine.

The Gastric Peristalsis or Motor Function of the Stomach.—This is perhaps the most important function of the stomach, for not only does the motor function mix and churn up the gastric contents, but it expels them at

the proper time into the bowels. An animal might live without a gastric secretion, or with a stomach which could not absorb anything, but it could not live with a stomach that had no peristalsis. The muscular layer of the stomach is much thicker and stronger at the pyloric end, which is near the outlet toward the intestine, than at the cardiac end, which is the dilated rounded pouch extending in the opposite direction. The cardiac end of the stomach is therefore mostly quiet during the digestive act, and the principal gastric movements of churning and expulsion occur in the pyloric end where the muscles are strongest. According to Oppel, the cardiac or quiet end of the stomach in certain animals, like the horse, pig and rat, is functionally distinct from the pyloric end. It is lined by a different kind of epithelium called pavement epithelium and its glands have no acid secretion. Accordingly this quiet region is, even under normal conditions, the seat of active starch digestion. It has been thought that, inasmuch as the starch-converting agency of the saliva could not act in the presence of an acid like that of the gastric secretion, therefore, all starch digestion was arrested in the stomach and was not resumed until the food reached the intestine. That this is not the case is shown by W. B. Cannon, who proved that in man as in other animals the cardiac end of the stomach serves chiefly for starch digestion by the action of the salivary ptyalin during the early part of digestion in the stomach. ('American Journal of Physiology,' Vol. VI, p. 396). This again emphasizes the importance of thorough mastication, for only thereby can the food be thoroughly penetrated by the saliva and further starch conversion take place in the cardiac end of the stomach during gastric digestion.

The movements which food undergoes in the stomach during digestion can be studied by the aid of the X-rays. An inert and insoluble substance which is capable of cutting off the X-rays must be mixed with the food in order to make the gastric movements visible before the Roentgen apparatus. Bismuth subnitrate answers this purpose admirably. Even the movements of the human stomach can be studied by adding this insoluble substance to the food and placing the individual who has eaten it before the X-ray instrument. In this way it has been discovered that the pyloric or highly muscular portion of the stomach is the part where the most effective gastric movements are brought about. The movements in the other portions of the stomach are not of sufficient force to be noticeable before the X-ray apparatus. It seems probable, therefore, that the fundus or pouch end of the stomach serves simply to push the food into the pyloric end, where it is churned to and fro for a while and eventually expelled into the duodenum. Three or four inches from the exit of the stomach, known as the pylorus, the musculature of the stomach is particularly strongly developed (sphincter muscle of the antrum pylori); and here it is that the stomach may constrict to such an extent as to partition off a special portion of the pyloric end and expel the food into the duodenum without permitting of any regurgitation into the fundic end. All this is in contradiction of the view originally held by Beaumont and still quoted in some of the

textbooks of physiology, namely, that there is a regular circuit of food around the walls of the gastric cavity.

Structure of the Stomach.—It is impossible to enter here into a consideration of the microscopic structure of the stomach, although this

important things to decide when an individual complains of dyspepsia, or of any distress, pain, distention or symptom referable to the stomach, is whether the signs and symptoms are really traceable to the stomach or not. For one may have all the symptoms of gastric

disease and yet the stomach itself may not be abnormal either in structure or function. For instance, the stomach may give rise to abnormal sensations as a consequence of disease of other organs. The organs which most frequently derange the stomach in this manner are the heart, liver and kidneys. Even physicians of experience who have become afflicted with abnormal gastric digestion have been at times deceived concerning the true source of their malady. Fully two-thirds of all gastric sufferers who come to special clinics devoted to diseases of the stomach are suffering not from any primary disease of the stomach whatever, but either from a nervous affection of the stomach or from one of the gastric derangements that are secondary to disease of other organs. Perhaps the most frequent of these disorders are those that are due to the nervous gastric affection, or as they are called, the *gastric neuroses*. To determine precisely the exact nature of an affection of the stomach, the chemical analysis and microscopic examination of known test-meals is indispensable. According to the gravity of the morbid condition, a heavy or a light test-meal is

is indispensable for the proper understanding of its abnormal functioning. Much is yet to be learned concerning the cells of the peptic glands and their function. It is certain, however, that the different products of the gastric secretion, the hydrochloric acid and the ferments, do not originate in the same cells, but that there are acid-producing cells and ferment-producing cells in the glands within the stomach. It is even conceivable that the different ferments of the stomach are produced by different cells. The organ is composed of five different coats. Passing from without inward, these are (1) the peritoneal; (2) the muscular coat, which is in turn composed of the longitudinal and circular layers; (3) a connective tissue layer; (4) a very small thin layer of muscular tissue, called the *muscularis mucosæ*, separating the connective tissue from the glandular layer; (5) the glandular layer itself, innermost of all. In addition to these structures the stomach is permeated by arteries and veins, a liberal network of lymphatics and is richly supplied with nerves. The glandular layer is bordered by a stratum of columnar epithelial cells.

The Abnormal Digestion of the Stomach; Gastric Diseases.—One of the first and most

given and a certain time after it is eaten the stomach tube is passed into the stomach and a certain amount of the gastric contents withdrawn for analysis. As long as this is not done, all deductions from the symptoms and signs alone are conjectural. That is not to say that the inferences drawn from test-meal analysis and microscopical examination of test-meals are always conclusive. It is frequently necessary to examine also the blood and the urine of the patient and even to examine the stools after certain test-meals. Recently the method of fractional analysis of test-meal samples drawn at short intervals has been rediscovered. In a way it is of interest to ascertain the time relations of the gastric secretion, that is, when it reaches its height. Clinically, however, the expediency, feasibility and possibility of this method are still *"subjudice"*. Then all the other organs of the body should be carefully examined, bearing in mind that it is not always correct to presume that a patient has a disease of his stomach because he has gastric symptoms. The reverse is equally true, that a patient may have no symptoms whatever referring to the stomach and yet have very grave disease of this organ. The gravest affection which may befall the organ—cancer of the

stomach—has been known to run its entire course and cause death in a latent manner; that is, without giving a single symptom referable to the stomach. This is an instance where a patient may have a gastric disease and no gastric symptom. A person who suffered from almost complete blindness, yet manifested no disease in his eyes, was found after exhaustive study to have been thus affected by a poison circulating in his blood, which was absorbed from his gastro-intestinal canal and was due to an abnormal digestion. Under treatment directed toward his stomach and intestine his vision gradually returned.

It is important to avoid aggravating an existing trouble by illogical and promiscuous medication, faulty diet and the use of alcoholic stimulants. Between 80 and 90 per cent of the so-called stomach tonics, liver regulators and stomach bitters are composed of alcohol. But even the prescriptions of physicians are not always adapted to the existing conditions. One of the most frequent abuses among practitioners of medicine is the indiscriminate dosing with mixtures containing pepsin. In a similar manner the ferments which convert the starches, the carbohydrates, into sugar, have been much abused. These substances are called *diastases*. Now diastase is a ferment with which the digestive tract is abundantly supplied. It exists in the saliva in the shape of a ferment called *ptyalin*, and in many hundreds of tests with human saliva it has been discovered in only 2 per cent of the cases that this substance was not secreted in sufficient quantity. It is conceivable, however, that in a mouth which has been made offensive by carious teeth, by a badly coated tongue, enlarged tonsils and catarrh of the mouth, throat and nose, this ptyalin can be destroyed and rendered ineffective; it can also be inhibited by the loss of alkalinity of the saliva in acidosis and gout. The proper thing to do then is not to give ptyalin or diastase in form of a medicine, but to cure the abnormal condition of the mouth and general system. A frequent form of gastric disturbance is called by general practitioners "amylaceous dyspepsia," which is an objectionable name given to the symptoms of hyperacidity and hypersecretion. This disease is frequently treated by cutting off the carbohydrates or starchy foods, which is irrational, because they cannot be dispensed with, not on account of the starch only, but on account of the proteid which amylaceous foods contain. It will be found from the army rations of men under service of various nations that the carbohydrate portion of the foods is increased with harder work much more than the proteid or fat portion. Therefore these foods should not be taken away because they may not be perfectly digested; but the cause of the indigestion should, if possible, be removed. If possible, a large amount of natural saliva should be swallowed after meals. Often it has been observed that with the simple supply of additional saliva caused by chewing a piece of rubber, etc., starch indigestion could not be demonstrated in the test-meal, although it had existed before. To Fothergill is attributed the saying that "ferments are crutches." No doubt many an invalid would prefer walking on crutches rather than not at all. But there are many crutch-walkers, who by modern surgery have been enabled to throw away the crutches and

walk unaided. So with the digestive ferments; they may be used with success temporarily, but the best thing to do is to discover how the patient may digest without them. And in case of amylaceous dyspepsia this is accomplished by cure of the excess of hydrochloric acid formation, or restoring the lost motor function of the stomach. For when the starchy foods are retained in the stomach overtime, they are very apt to cause an excessive secretion, or to produce an excessive amount of organic acid by fermenting in the stomach under the influence of bacteria.

In this connection it becomes a duty to warn against the use of *saccharin* as a substitute for sugar. As our nation is now engaged in the gigantic struggle to preserve its civilization, our government has found it necessary to restrict the sugar consumption. So far, fortunately, not under the caloric requirements for a human being. But to sweeten food and drink by *saccharin* is a mistake because this substance impairs the digestive power of the gastric juice—in fact, of all digestive ferments.

Instruction in Cooking Needed in American Schools.—One of the chief features in the treatment and also in the prevention of diseases of the stomach is the avoidance of improper medication and, what is even more important, of unsuitable diet. Much improvement is needed in American cooking and public kitchens and cooking schools might be of great benefit. Serious injury is being caused by insufficient or improper food. Instruction in cooking and diet should be given in all public schools where young girls attend. For nine out of 10 girls that attend these schools it will be a greater blessing, and they personally will prove a greater blessing to the community, if they know how to prepare a roast, boil potatoes and make an omelet or good bread, than if, ignorant in these things, they can give the most scholarly translation of Virgil. In Europe it is not considered below the dignity of daughters of the highest families, even those directly connected with royalty, to attend cooking schools. Nor is such an education incompatible with the best scientific and classical training. So the prevention of diseases of the stomach demands a wider and more thorough knowledge of the art of cooking. In addition to this, it necessitates a simpler life, closer adherence to the laws of nature, more freedom from business strain and nervous tension, and above all things the avoidance of excess in the use of alcoholic beverages and tobacco. Patients should be impressed with the fact that neither drugs nor any methods of treatment can improve them if they persist in their bad habits and faulty diet. Particularly must American business men, who, with admirable energy, but with little regard for their own health, persist in work too severe for their mental and physical constitutions, be taught that the prime factor in their successful treatment is rest. To such cases mental and physical rest is more essential to recovery than medicine or treatment directed to the stomach. Another factor which frequently leads up to stomach diseases is inactivity of the intestines, or constipation. This should in all cases of dyspepsia receive proper attention. When a person begins to feel distress after eating, or eructates, vomits, or has feelings of oppression, fulness or pain in the abdomen and headaches, one of the first

treatments that is usually given by sympathizing friends is a drink of some alcoholic beverage, usually whiskey; then comes the abuse of pepsin; very frequently the abuse of some combination containing soda and mint, or some widely advertised panacea for the diseases of digestion. All this is generally being done in the entire absence of a correct recognition of the real disease. The safest thing for the patient to do in the absence of a logical diagnosis is to rest the stomach absolutely for 24

due to disease of the structure of the gastric walls. In these cases there is, as a rule, no mechanical interference at the outlet of the stomach, or such interferences are secondary to some obstruction at the outlet. The causes of this obstruction may be scars from old gastric ulcers; tumors, especially cancers; indurative chronic gastritis; or any peritonitic inflammation which may constrict the stomach from the outside. Frequently gall-stones which result in pericystic inflammation may constrict

the part of the bowel immediately below the stomach in such a manner that it is indistinguishable from an obstruction of the pylorus. Five such cases are reported in 'Progressive Medicine,' by Prof. J. C. Hemmeter, December 1903, p. 45. So the cause of a dilated stomach is not always to be sought within the stomach itself.

A knowledge of displacements and dilations of the stomach necessarily precludes a knowledge of its normal position. This is admirably depicted in the accompanying illustrations where it is seen that the larger end of the stomach, or the blind pouch, may extend higher than the fifth rib, on the left side, thus reaching up behind the apex of the heart. This readily explains the distress felt about the heart, and also the irritable heart-action in some forms of gastric disturbance. The dorsal view of this illustration also shows the correct or normal relations of the 10th rib just referred to in connection with gastropotosis. When the 10th rib is detached or floating its tip sticks out like that of the 11th rib in this illustration. The same illustrations also demonstrate the anatomical fact that only a very small portion of the stom-

to 48 hours, and not take any food or medicine whatsoever; and thereafter, beginning with the very simplest kind of food—a small plate of farina, of strained oatmeal, a piece of toast, and a cup of hot milk and lime-water—proceed gradually to a cup of bouillon, and a small slice of lean boiled beef. Alcohol, sugars, rich and fatty substances should be avoided for a long time.

Organic Diseases of the Stomach.—These are the various forms of gastritis (catarrh of stomach, ulcer, carcinoma, etc.) and the displacements and enlargements, dilatation. Displacements—gastropotosis—may be congenital or acquired. When the stomach is displaced from its normal position, the condition is in the great majority of cases accompanied with an infirmity of the general nervous system known as neurasthenia (q.v.). Stiller has pointed out that this condition in over 80 per cent of these cases is attended by the loose or floating 10th rib. Normally the 10th rib is attached to the costal cartilages, and these to the breast-bone. But whenever the stomach is displaced out of its normal position and a very diffused splashing sound is audible over the abdomen on shaking the stomach, there is, as a rule, a very movable or floating 10th rib.

Dilatations of the stomach may be primary,

ach is palpable through the soft part of the abdominal wall, when it is in normal position, because the larger part of it is concealed under the ribs and under the liver. So that the simple fact that we can see or feel a large part of the entire stomach projecting through the abdominal wall, when it is distended, is a sufficient evidence that the stomach is out of place. The stomach can be made visible through the abdominal wall by distending it artificially with carbon dioxide by means of an effervescent mixture containing tartaric acid and bicarbonate of soda. Hemmeter was the first to propose and use a method for locating and determining the size of the human stomach by successful use of the X-ray (*Boston Medic. and Surg. Journal* 1897), and later another method for recognizing gastric ulcer by means of radiography ('Archives of Digestive Diseases,' Berlin 1906).

The remaining organic diseases of the stomach necessitates all the intricacies of chemical and microscopical diagnosis for their detection. They include the various forms of acute and chronic gastric catarrh or, as they should preferably be called, the forms of acute and chronic gastritis, the various types of gastric or peptic ulcers, the various tumors of the stomach,

especially cancer, which is becoming more and more frequent. Then there are numerous diseases of a general nature, such as tuberculosis, typhoid fever, glanders, lymphadenoma and syphilis, to be considered in the study and treatment of disorders of the stomach.

When ever there is an organic disease of the stomach present it should be sought after with all the resources of modern clinical diagnosis. There should be no dallying with so-called stomach panaceas. Quite a number of the so-called incurable gastric diseases which have been allowed to go on to destruction of the glandular layer and absolute loss of peristalsis of the stomach are not incurable in themselves, but have become so from neglect, maltreatment, or procrastination. And even in those cases in which the practitioner is at present helpless, the rapid progress of medical art, especially as applicable to digestive diseases, promises a substantial gain in the near future.

Bibliography.—Hemmeter, 'Diseases of the Stomach,' in which there are 1,288 separate publications arranged categorically in separate chapters to which they refer especially, and over 1,000 references in the text; Ewald, 'Diseases of the Stomach,' translated into English by Morris Manges; Boas, 'Diagnostik und Therapie der Magenkrankheiten'; Riegel, 'Erkrankungen des Magens,' being Vol. XVI of Nothnagel's 'Encyclopedia on special Pathology and Therapy'; Stockton, 'Diseases of the Stomach'; Fleiner, 'Krankheiten der Verdauungsorgane'; Einhorn, 'Diseases of the Stomach'; Martin, 'Diseases of the Stomach'; Abercrombie, 'Investigations on Diseases of the Stomach'; Habershon, 'Diseases of the Abdomen'; Rosenheim, 'Pathologie u. XII (article on indigestion by G. LeMoine).

JOHN C. HEMMETER, M.D.,

Professor in University of Maryland, Baltimore.

STOMACH-PUMP, a small pump or syringe used for removing matter from the stomach, for washing it out, or for injecting fluids into it. It resembles the common small syringe, except that there are two apertures near the end, instead of one, which, by means of valves in them opening different ways, serve respectively as a sucking and a forcing passage. When the object is to extract something from the stomach, the pump is worked while its sucking orifice is in connection with an elastic tube passed into the stomach; and the extracted matter escapes by the forcing orifice. When it is desired to throw cleansing water or other liquid into the stomach, the connection of the apertures and the tubes is reversed. A pump may not be always procurable when the occasion for it arises, and a simple tube will in many cases answer the purpose as well, if not better. If the tube be introduced and the body of the patient be so placed that the tube forms a downward channel from the stomach, all fluid matter will escape from the stomach by it, as water escapes from a funnel by its pipe; and if the outer end of the tube be im-

mersed in liquid, there will be, during the discharge, a siphon action of some force. On changing the posture of the body, water may be poured in through the same tube to wash the stomach. For washing out the stomach a long flexible tube is also in common use, water being run in by means of a funnel attached to one end, and this end being afterward lowered so as to form the tube into a siphon.

STOMATA (Greek *stoma*, mouth), minute orifices or pores in the epidermis of leaves, etc., which open directly into the air cavities pervading the parenchyma. The stomata are also called the "automatic gateway." See LEAVES.

STOMATITIS. See MOUTH, DISEASES OF THE.

STONE, Amasa, American business man and philanthropist: b. Charlton, Mass., 27 April 1818; d. Cleveland, Ohio, 11 May 1883. At 21 he engaged in the construction of railroad bridges and railroads, and soon attained high rank among constructors. In 1846 he entered into a partnership for the building of the Cleveland, Columbus and Cincinnati Railroad; in 1850 he was president of that road and thenceforward resided in Cleveland. He was later engaged in the construction of the Cleveland and Erie Railroad; was managing director of the Lake Shore Railroad in 1872-74; and was president or director of several railroads and industrial corporations in Ohio. He gave largely to charitable institutions in Cleveland, and built and endowed an old ladies' home and an industrial school. He also gave to Western Reserve University, \$600,000, on condition that the university should be moved from Hudson to Cleveland, and that the classical department should be named in memory of his son, Adelbert College. Consult 'Amasa Stone, A Memorial' (New York 1883).

STONE, Charles Pomeroy, American soldier: b. Greenfield, Mass., 30 Sept. 1822; d. New York 24 Jan. 1887. He was graduated from West Point in 1845; served in the Mexican War and was brevetted captain. He became chief of ordnance of the division of the Pacific and subsequently settled in California. At the opening of the Civil War he was an officer of volunteers in the Union army, but after a short term of service was arrested, and imprisoned in Fort Lafayette, New York harbor, February-August 1862. Upon his release he served in the Department of the Gulf, and was chief of staff to General Banks, 1864-64. Later in the year he resigned from the army and entered the service of the khedive of Egypt in 1870 where he rose from brigadier-general and chief of staff to be Ferik-Pasha (1873-83). He received numerous decorations and held confidential positions under the khedive. Returning to the United States he became the engineer in charge of building the foundation for the Statue of Liberty in New York harbor.

STONE, Edward James, English astronomer: b. London, 1831; d. Oxford, 1897. He was graduated from Queen's College, Cambridge, and in 1860 was appointed chief assistant at the Greenwich Observatory. In 1870 he was made royal astronomer at the Cape of Good Hope, in which position he prepared a catalogue of all stars to the 7th magnitude between the south pole and 25° S. declination. For this he

was awarded the Lolande prize of the French Academy in 1881. This he supplemented in 1891 by a catalogue of all stars to the 7th magnitude between 25° S. declination and the equator (6424). In 1879 he was appointed Radcliffe observer at Oxford, a position he held till his death. Among his contributions to astronomical science were his deduction of the value of the solar parallax and his observation of the reversal of the Fraunhofer spectrum during an eclipse of the sun in 1874. Consult Royal Society, 'Catalogue of Scientific Papers' (London 1867-1902).

STONE, Ellen Maria, American missionary: b. Roxbury, Mass., 24 July 1846. She was a member of the staff of the 'Congregationalists' at Boston in 1867-68, in 1878 went to Samokov as a Congregational missionary, and was removed subsequently to Philippopolis, southern Bulgaria, and (1898) Salonica, Macedonia. In September 1901 she was kidnapped by brigands between Bansko and Djumia, Macedonia, and a ransom of \$110,000 for her and Mme Tsilka, captured at the same time, was demanded. By subscription in the United States, \$65,000 was raised and the release of the prisoners followed. Her narrative appeared as 'Six Months Among Brigands' in *McClure's* in May-October 1902, and in 1903 in book form. Later on she lectured in order to raise money for foreign missions. She also contributed to magazines and newspapers.

STONE, Frank, English painter: b. Manchester, 22 Aug. 1800; d. London, 18 Nov. 1859. He originally painted in water colors, and in 1837 became a contributor to the exhibitions of the Royal Academy. Subsequently for more than 20 years he produced many works in genre and history, and on subjects of sentiment and imagination. Some of these are well known by engravings, particularly the companion pieces entitled 'The First Appeal' and 'The Last Appeal,' once very popular. He was elected an associate of the Royal Academy in 1851.

STONE, Harlan Fiske, American law scholar and educator: b. Chesterfield, N. H., 11 Oct. 1872. He was graduated at Amherst College (1894), received the degree LL.B., Columbia University of Law (1898), and LL.D., Amherst (1913). He was admitted to the New York bar in 1898, was lecturer on law (1899-1902), professor of law (1902-05) and was dean from September 1910, of Columbia University School of Law. He is a member of the law firm of Satterlee, Canfield and Stone. He wrote 'Law and its Administration' (1915).

STONE, James Samuel, American Protestant Episcopal clergyman: b. England, 27 April 1852. He was graduated from the Philadelphia Divinity School 1877, took orders, and was rector of Saint Philip's Church, Toronto, 1879-82, of Saint Martin's Church, Montreal, 1882-86, of Grace Church, Philadelphia, 1886-95, and of Saint James' Church, Chicago, since 1895. He was made B.D., by the Cambridge Theological School, and D.D., by Bishop's College, Lennoxville, Canada. He has published 'Simple Sermons on Simple Subjects' (1879); 'The Heart of Merrie England' (1887); 'Readings in Church History' (1889); 'From Frankfurt to Munich' (1894); 'Woods and Dale of Derbyshire' (1895); 'The Prayer

before the Passion' (1911); 'The Passion of Christ' (1912); 'The Glory After the Passion' (1913); 'The Preparation for the Passion' (1915).

STONE, John Timothy, American Presbyterian clergyman: b. near Boston, 7 Sept. 1868. He was graduated (class orator) at Amherst College (1891) and at Auburn Theological Seminary (1894). Served as pastor at Utica (1894-96), Cortland, N. Y., (1896-1900), Brown Memorial Church, Baltimore (1900-09), and, since 1909, at Fourth Church, Chicago. He was moderator of the General Assembly of the Presbyterian Churches in United States, 1913-14 and president of trustees of the College of Wooster from 1917. During the World War he was Captain-Chaplain of Illinois Reserve Militia, First Infantry, and director of Y. M. C. A. religious work at Camp Grant, Ill. He has written 'Footsteps in a Parish' (1908); 'Recruiting for Christ' (1910), as well as monographs on themes educational and religious.

STONE, Lucy Blackwell, American reformer: b. West Brookfield, Mass., 13 Aug. 1818; d. Boston, 18 Oct. 1893. She was graduated at Oberlin College in 1847 and in 1855 was married to Dr. Henry B. Blackwell, retaining, however, her own name. In 1848 she toured the New England States and Canada lecturing against slavery. In 1869 she helped organize the American Woman's Suffrage Association of which she was president until 1872; became connected with the *Women's Journal* in 1872, and was editor after 1888. Her lectures on woman suffrage made her known throughout the country.

STONE, Marcus, English painter: b. London, 4 July 1840. He is a son of Frank Stone, A.R.A. He learned his art in his father's studio; exhibited his first picture in 1858 in the Academy, of which he became an associate in 1877, being elected an academician in 1887. Among his better-known pictures are 'Claudio Accuses Hero'; 'On the Road from Waterloo to Paris'; 'Stealing the Keys'; 'Henry VIII. and Anne Boleyn'; 'Sain et Sauif'; 'Il y en a toujours un autre'; 'A Gambler's Wife'; and 'The First Love Letter.' Many of his pictures have been published as engravings and in this form have become well known to the public.

STONE, Marvin Cheater, American inventor: b. Portage County, Ohio, 1842; d. Washington, D. C., 17 May 1899. He invented several small articles, and afterward discovered a method of imitating, in colored china, the famous "peach-blow" vase. He acquired a large fortune, and during his later years was engaged in many philanthropic undertakings.

STONE, Melville Elijah, American journalist: b. Hudson, Ill., 22 Aug. 1848. He began his journalistic career on the *Chicago Tribune*, but was not permanently settled in it until 1871, when he established the *Chicago Daily News*. In 1881, with Victor F. Lawson, he acquired the *Chicago Morning News*, changing its name to the *Record*. In 1888 he retired temporarily from newspaper work, and spent some years in Europe, and upon his return entered the banking business, organizing the Globe National Bank (1891) of which he was president until

its consolidation with the Continental Bank in 1898, when he became general manager of the Associated Press.

STONE, Ormond, American astronomer: b. Pekin, Ill., 11 Jan. 1847. He was educated at the University of Chicago, and in 1870 was made assistant astronomer at the Naval Observatory at Washington. From 1875 to 1882 he had charge of the Cincinnati Observatory superintending among other works an extended series of measures of Southern double Stars. From 1882 to 1912 he was professor of astronomy and director of the observatory at the University of Virginia, where he devoted himself principally to the observation of nebulae and variable stars. As a teacher he trained a large number of astronomers. He founded and edited the *Annals of Mathematics*; contributed to various scientific journals, and devoted much of his time to the cause of public education. In 1912 he retired on a pension from the Carnegie Foundation.

STONE, Thomas, American patriot, signer of the Declaration of Independence: b. Pointon Manor, Charles County, Md., 1743; d. 5 Oct. 1787. He studied law at Annapolis, and began to practice at Frederickton in 1764. He was a delegate to the Continental Congress in 1775-77, and served as a member of the Committee on Confederation (1776-77). In 1777 he urged Maryland to ratify the Articles of Confederation, which, however, the State did not do until three years later. In 1783-84 Stone was again a delegate to the Continental Congress, and in the latter year acted as president *pro tempore*. Consult Sanderson, 'Signers of the Declaration of Independence,' Vol. IX (1823-27).

STONE, Walter King, American illustrator: b. Barnard, N. Y., 2 March 1875. He was educated at the Rochester public schools, studied at Rochester Mechanics' Institute and Pratt Institute, Brooklyn. He has been illustrator and designer for *Century*, *Harper's*, *Scribner's*, *American*, *Delineator*, etc., besides designing numerous book-covers.

STONE, Warren Sanford, American labor leader: b. Ainsworth, Iowa, 1 Feb. 1860. He was educated at Washington Academy and Western College. He started service (1879) with the Rock Island system railroad as fireman and was promoted to engineer in 1884. He was appointed (1903) grand chief of the International Brotherhood of Locomotive Engineers (succeeding grand chief Arthur) and has held this office ever since. He is a member of the Industrial Peace Commission.

STONE, William Joel, American lawyer and statesman: b. near Richmond, Ky., 7 May 1848. He studied law and was admitted to the bar in 1869 and began to practice at Nevada, Mo., in partnership with Judge C. R. Scott. In 1872 he was elected prosecuting attorney at Vernon, County. He was Democratic Congressman from the 12th Missouri district from 1884-90, and was elected governor of Missouri in 1892. In 1903 he was elected to the United States Senate receiving re-election 1908 and 1914. He became chairman of the committee on foreign relations after 1913 and was one of those few who advocated that Americans should be warned against sailing on ships of the belligerents.

STONE, William Leete, American historical writer: b. New York, 4 April 1835; d. Mount Vernon, N. Y., 11 June 1908. He graduated from Brown University in 1858 and in 1859 was admitted to the bar. He was centennial historian for New York and made the speech at Independence Hall, 10 May 1876. He published 'The Life and Times of Sir William Johnson, Bart'; 'Revolutionary Letters'; 'History of New York City'; 'The Saratoga Battle Grounds'; and 'Life of Governor George Clinton.'

STONE, Witmer, American naturalist: b. Philadelphia, 22 Sept. 1866. He was educated at the University of Pennsylvania, and was assistant curator in charge of the museum of the Academy of Natural sciences, Philadelphia. He has published 'Birds of Eastern Pennsylvania and New Jersey' (1894); 'Mammals of New Jersey' (1908); 'Birds of New Jersey' (1909); 'Flora of Southern New Jersey' (1912); 'Birds of Yucatan and Southern Mexico'; 'The Molting of Birds', etc.

STONE. (1) A small piece or fragment of rock; a piece of rock adapted in size and shape for a specific purpose, as for building, etc. (See BUILDING MATERIALS; ROCKS; GRANITE; MINERAL PRODUCTION OF THE UNITED STATES). (2) In medicine, a calculus concretion in the bladder, kidney, etc. (See CALCULUS). (3) A denomination of weight. See WEIGHTS AND MEASURES.

STONE, Artificial. See CEMENT; CONCRETE; MASONRY.

STONE AGE, the name given to that period in the development of prehistoric mankind when stone, bone, shells and wood were the only materials employed as tools, weapons, and implements. The term first came into recognized use by the publication in 1865 of 'Prehistoric Times,' written by Sir John Lubbock (Lord Avebury), who compiled and set in order the discoveries made in France and elsewhere during the previous half century. He classified the prehistoric period into three divisions, namely: *Iron Age*, when bronze, copper and stone were superseded by iron in most instruments and weapons, continuing to the present; *Bronze Age*, preceding the use of iron, when bronze was the predominant material; and *Stone Age*, still earlier, in which, until near its close, no metal was made use of by men.

The Stone Age was further divided by Lubbock into 1. *Paleolithic*, Old Stone Age, the more ancient time of chipped stone implements; and 2. *Neolithic*, New Stone Age, the more recent time of polished stone implements. This classification persists, but further collection of materials has enabled archaeologists to define several subdivisions, especially in the Paleolithic part, marking successive changes in the population and advances in culture, at least in southern and western Europe. Elsewhere there seems never to have been such a concentration of primitive humanity, nor have its remains been so thoroughly studied; nevertheless it is possible in a general way to arrange the facts gathered in all parts of the world into the European culture-scheme. Chronologically, however, this cannot be done. Some peoples learned how to

smelt and forge iron long before others; bronze was made and cast in some countries earlier than in others; and meanwhile races and tribes elsewhere continued in ignorance of either. In fact, savage peoples in remote corners of the world remain in the Stone Age to the present time, and will continue to do so indefinitely, except for such improvements as they may adopt from more enlightened neighbors. The succession of stages in cultural evolution to be outlined in this article nevertheless accords with the truth as applied to any one region or race, because there is never a retrogression from a higher to a lower stage. At the same time it seems probable that the significant advances were not often, if ever, by slow evolution, but rather were owing to the conquest and occupation of each country by strangers bringing some superior degree of culture.

Paleolithic or Old Stone Age.—It is hardly a century since the chance finding of an arrowhead unmistakably of human workmanship (i.e. an artifact) deep in the gravel of the Somme Valley, in France, led to an immediate and lively interest in the new science of prehistoric anthropology, and to extended explorations not only in France but all over the world. This soon resulted in large collections of objects picked up on the surface, taken from various depths in river-sands and gravel-deposits, or found in caves, peat-bogs, graves, etc. These were attentively studied not only with reference to material, form and possible purpose, but in the light of geography and geology, in order to determine their relative age. The determination of the geological position in which each relic was found was particularly important. The general result of 50 years of study has been the perception and arrangement of the following series of culture-groups, or "stages", within the Paleolithic period, numbered from the oldest (1) to the most recent (8):

- | | |
|-------------------------|----------------|
| 8. Azilian-Tardenoisian | 4. Mousterian |
| 7. Magdalenian | 3. Acheulian |
| 6. Solutrean | 2. Chellean |
| 5. Aurignacian | 1. Prechellean |

A brief account of the geological record is here necessary in order to place the earliest traces of man in the Stone Age in proper perspective. All readers are probably acquainted with the fact that an era of intermittent glaciation that in its maximum effects covered nearly all of the northern hemisphere with an arctic climate and thick ice, intervened between the close of the Tertiary (Pleistocene division) and the beginning of the Quaternary era, which latter immediately preceded the present conditions. This Glacial Period, as it is termed, is now known to have been not continuous, but to have had—at any rate in Europe—three breaks, during which intervals the ice disappeared and a mild climate prevailed. This amelioration was most marked following the second ice-period, when for an immensely long time both Europe and North America were restored to a climate and appearance not greatly different from the present. Forests and vegetation were much the same as now, and most of the animals, with the addition (perhaps implying a somewhat warmer climate)

of hippopotami, elephants, rhinoceroses, lions, and some other now tropical species, all long ago extinct.

Eolithic Relics.—In geological formations of this "Eolithic" time have been found rudely chipped and hammered stones that are regarded by most archaeologists as true artifacts, and are called "eoliths." It is very likely that some of them are really of human handiwork; and it is believed by many persons that an indication of their makers is given by the discovery, in 1907, deep in a gravel-bed near Piltdown in Kent, England, of a broken, fossilized skull having human characteristics. Piltdown is on a plateau abounding in eolithic flints and broken pebbles. This skull has been the subject of intense study and discussion. All its features, as well as the brain capacity, denote a being inferior to any other prehistoric race known; but its relationship to them, or to the more recent inhabitants of the globe, remains undetermined; it is not, in fact, fully conceded to be anything but the braincase of an anthropoid ape. These rude relics of the dawn of humanity mark the *Pre-Chellean* stage; and the situation implied would be dubious were it not that in some places the accompanying implements are convincingly of human workmanship, and were it not that an indubitable relic of a human frame has been exhumed: for in the sands of Maurer, near Heidelberg, Germany, there was found, in 1907, a human lower jaw, which is the oldest or earliest known representative of the human race. This Heidelberg man (*Homo heidelbergensis*) had many apelike features, but he was unmistakably human, and his period is estimated at 250,000 years ago.

Pre-Chelleans.—This long warm period was followed by one of great aridity, changing latterly into a moist, cooling phase that brought a renewed glaciation, which, however, did not extend nearly as far toward the south as has the earlier ones; and after a time the glaciers again retreated, and a third warm stage renewed livable conditions throughout the North Temperate Zone, so that southern Europe and northern Africa again became occupied by human inhabitants. They were nomadic savages, no doubt, wandering along the river courses; and they possessed so little ingenuity that they were able to improve very little the shapely pebbles, or accidentally fractured flints and other sharp-edged stones that they picked up and tried to use as aids to their hands. That these rude Pre-Chellean forerunners of mankind existed for an immensely long time, and became widely diffused, is shown by the fact that in every part of the world their rough implements are to be found, substantially alike whatever the region.

Chellean Stage.—The first indication of advance is that stage called *Chellean*, in which men had not only improved in the shaping of flint pieces to service, but invented new tools. Its characteristic implement is the "hand-ax" (*coup de poing*, of the French), in which an elongated pebble of flint or quartzite was flaked by chipping it on both sides to a point at one end, while usually the natural roundness of the stone was left at the other. This tool was roughly almond-shaped, of any convenient size, and was grasped in the palm of the hand, it having no other sort of a handle.

Acheulian Stage.—A more advanced stage of this industry is marked particularly by the earliest evidence of knowledge how to kindle a fire—probably the most momentous single discovery in human history. The flaked flints and other worked-stones of this culture-stage are much superior in both form and variety of utility to those of the Chellean, and represent a really remarkable advance in intellectuality and in breadth of life. This Acheulian period was brought to an end, slowly but steadily, by the approach of the fourth recurrence of glacial cold in Europe, after a third interglacial, or warm, interval of about 125,000 years, during which man had progressed in industry from Pre-Chellean inability to the excellence of Acheulian productions, which imply a very considerable elevation above a mere animal existence.

Mousterian Stage.—The arid and steadily cooling climate of Acheulian times was followed, as has been stated, by a fourth glaciation, equivalent to what in North America was the last and greatest "glacial period," when one ice-cap covered all Europe north of the Baltic, and another spread far outward from the Alps; and the climate was, of course, exceedingly cold. This is the "Reindeer Period" of the older writers on prehistoric antiquities, a name suitable enough since that and other boreal animals characterized the semi-arctic fauna of all the North Temperate Zone. During this cold time, estimated to have lasted 25,000 years, man continued to exist in what is termed the *Mousterian* stage of culture; but under the hard conditions of life at that time mankind deteriorated, judging by the inferiority of his tools as compared with those of his Acheulian predecessors. His relics are found most abundantly in southern Europe, and in caves, which were then first resorted to as permanent human habitations, the wintry weather driving men to seek their snug shelter. The *Mousterian*, then, is the true "cave-man." What he was like is known from a great number of skulls and other parts of skeletons exhumed from cave-floors and other subterranean deposits of this time. The first important find of the kind was in 1856 in a grotto in the Neanderthal (Neander Valley) near Dusseldorf, Rhenish Prussia; but since then skulls and other bones in excellent preservation have been procured at Canstatt in Germany, Spy in Belgium, Sipka in Moravia, Krapina in Croatia, and at many places in southern France, especially in the caves at Le Moustier in Dordogne, from which the period derives its name.

Neanderthal Cave-Dwellers.—Southern France, a limestone region, is honeycombed with caves (see *CAVE-DWELLERS*), and seems to have been the most populous centre of the Neanderthals (q.v.)—an intermediate race that extended from England to Hungary, at least, and were the typical savages of Paleolithic times. They were men of a species (*Homo neanderthalensis*) superior to the Heidelberg type of Chellean times (possibly their ancestor), but retained apelike characteristics, and certainly were far inferior in physique, as in mind, to the Neolithic men, presently to be described. The skull of the Neanderthal man was characterized by an extremely receding forehead, by the great ridges of bone above the eyes, a massive jaw with little chin, and very strong

teeth and chewing-muscles, indicating that these ancient people were meat-eaters. They were men of stocky, robust frames, averaging about five feet and four inches in height, but they had not yet acquired a fully erect attitude of body.

The relics of the earlier part of the *Mousterian* period show little advance over the preceding culture; but later the increased employment of the sharp, knife-like flint-flake, retouched on one side only, is observable, and a gradual increase in the making of different hunting-weapons, and of small awls, scrapers and so forth, of stone and bone, and of needles necessary to sewing the skin clothing required in the colder weather of that time as compared with the era of their remote forefathers. Is it not possible that the improvement noted may be the result of the greater wants to be filled, and energy required thereby, owing to the increased difficulty of maintaining existence and comfort in a cold world? No evidence that these cave-men had or knew of the bow and arrow has yet come to light.

As the glaciers of this *Mousterian* period of cold, which lasted many thousands of years, melted, returning warmth of climate introduced the post-glacial conditions that with minor changes have continued to the present. It was at this juncture that the Neanderthal race came to an end, and did so with a relative suddenness that is astonishing. The latest student of the matter, Prof. H. F. Osborn, regards it as a case of the complete extinction of a species. "So far as we know at present," he declares, "the Neanderthals were entirely eliminated; no trace of the survival of the pure Neanderthal type has been found in any of the Upper-Paleolithic burial-sites." With their disappearance ends the *Mousterian* stage, and the Lower-Paleolithic period.

The Upper Paleolithic.—In the strata overlying that in which the relics of the *Mousterian* or Cave-man culture are found, lie the evidences of a new and different kind of industry, which introduces the Upper-Paleolithic division of the Old Stone Age.

This is known as the *Aurignacian* culture, and is attributed to the immigration into western Europe of a race of men, probably from the southeast, as *Aurignacian* relics are found on all the shores around the Mediterranean Sea. The inroad of these foreign and better-armed people was followed by the destruction of the race of Cave-men, whose grottoes and rock-shelters were adopted as homes by their conquerors. This happened, it is believed, between 25,000 and 30,000 years ago. Who were these strangers? Whence did they come? It is believed that they were Asiatics who had slowly worked their way westward chiefly, if not wholly, along the southern shore of the Mediterranean into and beyond Spain. They were true men—*Homo sapiens*—not intermediate in structure and ability between human and simian, as were their predecessors in Europe. In short they are the ancestors of a large part of the men of to-day, and it is unfortunate that they are not known by a better name than "*Cro-Magnons*"—the designation of the cave in Dordogne, France, where their first-known skeletons were obtained. They were tall, well-built men, with heads long fore and aft (*dolichocephalic*), and

with broad faces, pleasing features and well-developed chins. Probably the complexion of the skin was dark. They were men of large brains, a race, in Osborn's opinion, "capable of ideas, of reasoning, of imagination, and more highly endowed with artistic sense and ability than any uncivilized race which has ever been discovered." A large volume would be needed to describe thoroughly all of their industrial and social life as shown by the relics of the four successive stages of culture into which their long history has been divided by archæologists. It must be summarized here in a few paragraphs.

The Cro-Magnons.—The Cro-Magnons were essentially hunters, living on the flesh of wild beasts, including the mammoth, an extinct rhinoceros (elasmotherium), aurochs, wild horse and other animals of the forests and plains. They dwelt not only in caves and rock-shelters but in great winter-camps, where they built clusters of houses made of timbers and covered with hides, many sketches of which they have left for our information. But they were nomads, and in summer wandered in hunting and fishing bands, for there is no evidence that agriculture was practised. They had excellent weapons of chipped stone for both warfare and hunting, and probably used bows and arrows. They made various hooks and spears for fishing, and tools of stone, bone and horn for the preparation of skins, for sewing and other household purposes; but they made no pottery. In some regions they advanced in culture more than elsewhere. They spread in Aurignacian times from the upper Danube in the East to Belgium and Britain in the West, but southern France was the most populous. There it was that their life came to be most settled, and the extraordinary art that distinguished the Aurignacian time was most highly developed. The soil of the caves occupied by the people of this period, and the sites of their camping-places, abound in small flint-flakes carefully pointed into delicate engraving tools—among them one shaped just like a modern burin. It was with these gravers that they cut from ivory and soapstone statuettes of animal and human figures, or incised on slabs of slate, tusks, flat bones, antlers, and especially on the walls of grottoes, pictures of the beasts about them, scenes of the chase, drawings of their houses, etc., sketched not only with startling fidelity to nature but with an artistic sense marvelous in the circumstances. They had a love of beauty, an instinct for true art, which led them to try to ornament everything they used; and this art was steadily cultivated and developed until it reached its astonishing culmination in Magdalenian times. The cutting out of figures in bas-relief from stone surfaces (usually a cavern wall), and the modeling of statuettes, are distinctively Aurignacian; and in this stage, also, painting had its birth, for many of the colored drawings that adorn the walls and ceilings of the caves date from this period—for examples, the red-outlined bison and aurochs in the grotto of Castillo, Spain, and the spirited drawings in red ochre of the woolly rhinoceros, and of a stag in the cave at Font de Gaume, France. In many cases the Aurignacian artist carved the outlines and distinguishing features of his subject in deeply in-

cised lines, with minute attention to characteristic details. Therefore zoologists find some of these portraits of animals valuable to them, particularly with reference to the history of horses in Europe. The picture whose outlines were thus engraved was then coated with a reddish or yellowish paint composed of ochre and manganese mixed on a palette of schist.

Solutrean Culture.—The Aurignacian stage was succeeded by the *Solutrean*. This horizon is distinguished by the presence in its remains of the most delicately and perfectly worked leaf-shaped flints for knives, heads of spears, javelins and arrows, and in general by a sudden great improvement in the manufacture and design of all objects made of flint or quartz. This skilful culture, evidences of which are spread from the lower Danube Valley to the Bay of Biscay, is believed to be the product of fresh immigration of people from the teeming East, who moved westward along the northern border of the Black Sea and advanced up the Danube Valley and finally became predominant in southern Europe; yet it seems plain that the Cro-Magnons were not utterly destroyed even there, and that both in northern Europe and south of the Pyrenees they persisted in force. These invading Solutrean folks, who take their name from a vast camp, ringed with the turf-covered bones of tens of thousands of horses, slaughtered for food, near Solutré in southern France, were a practical people, ruder than those they had overcome, and during their time art declined.

Magdalenian Culture.—Comparative refinement revived, however, during the succeeding stage, the Magdalenian, when art was developed to its highest perfection in prehistory. Whatever may have been the racial character of the Solutrean people, the Magdalenean folk were unquestionably of Cro-Magnon stock. What was the occasion of the change that archæologists note at this point can only be conjectured, but the fact is plain. These Magdalenian Cro-Magnons attained in this period their highest culture and widest dispersion of the race. They have been traced northward to England and central Belgium, and eastward throughout central Germany, but never, apparently, colonized Italy or southern Spain. They were, as before, a nomadic and hunter people; but by this time the cold, wet climate had gradually softened into a warmer and drier one, and the growth of dense forests everywhere made the chase more and more difficult and arduous. Moreover the animals going in herds, such as the reindeer, wild cattle and horses, that needed large open grazing areas, had departed. In conformity with this the Magdalenians gradually became less nomadic, and depended more on fishing than on hunting for subsistence. Under these sedentary and softening influences the craft of the flintworker declined, for only poor and simple kinds of stone implements are recovered from village-sites of this time of decay; but the village-sites yield great numbers of skilfully contrived hooks, harpoon-heads, and other fishing-tools, chiefly made of bone. The style is quite new, and now are first seen round and barbed bone spearheads, the earliest with only an experimental barb, but later always furnished with rows of recurved barbs along their sides.

In this quieter life, where in the long-settled,

favorable and populous districts of southern France and the neighboring border of Spain the people must have obtained a firm tribal organization, the Magdalenians acquired that power of draftsmanship, sculpture and painting that has astonished the critical world, and has been illustrated so thoroughly in several recent books, as those of Sollas, Elliot and Osborn, and in the Annual Reports of the Smithsonian Institution, not to mention the many learned writings in French, Spanish and German. Nearly all the finest painting of this period as well as that of the Aurignacian artists is on the walls and ceilings of deep and totally dark caverns—a fact that has caused much speculation as to the motive that carried such art into places where the work could be made or observed only by lamplight. "It would appear," remarks Osborn, "that the love of art for art's sake . . . together with the fine spaces which these caverns alone afforded for large representations, may be an alternative explanation."

Azilian-Tardenoisian Invasion.—The decline of the Cro-Magnons may have been owing largely to environmental causes; but it may have been accelerated by the arrival, probably occasioning long battling, of two streams of newcomers, one of which, known as the Azilians, spread all over France and Belgium, and the other, the Tardenois, occupied Spain at first, but gradually coalesced with the other. Their flints are small and peculiar, totally unlike anything used by the Cro-Magnons. This may have been the result of a necessary change in the character of hunting weapons, for now southern Europe was covered with heavy forests, the reindeer had retreated to the North and the stag was the principal game-animal; in fact the people seem to have depended mainly on fishing for subsistence. The climate was still cool and moist, and therefore the use of caves and rock-shelters continued, but otherwise the habits and culture of these final races of Paleolithic man in southern Europe were totally different from, without being much in advance of those of the Magdalenians. Who were these final Paleoliths? The Azilians were a brachycephalic people, the first of that type to appear in the West; and it is believed that they may represent the first-comers of the Alpine, or Celtic, race of modern ethnology. They are often designated as the Furfooz stock. The other was a long-and-narrow-headed race that came in from northern Africa via Spain, and are thought to represent the earliest indication of what Sergi calls the Mediterranean race. It is evident that both were mentally superior to, and more broadly cultivated than, the Cro-Magnons, except in artistic matters, and subdued the latter completely; yet there is evidence that in southern France, at least, large communities of Cro-Magnons continued to live and develop, and have persisted there to the present day. After a few centuries, however, these Azilian-Tardenois men, the last of the purely hunting-races, themselves suffered displacement by the incoming of a more advanced people moving westward along the great Mediterranean highway of migration, and with their disappearance the Old Stone Age comes to an end.

Neolithic, or the Age of Polished Stone.—The notion formerly prevalent that there was a sudden clearing away of Paleolithic men and

things, and an equally sudden supercession of Neolithic people and culture, has been abandoned before the progress of information. Men in different parts of the world have always advanced toward better conditions at an unequal pace; and in most cases, as, for example, our North American Indians, who at the time of their discovery by Europeans were in the Neolithic stage, no evidence can be found of just how or when the advanced step was taken. In southern Europe, where circumstances favor a clearer local understanding of prehistory, it appears probable that between 7,000 and 10,000 years ago strangers began to filter in from the eastward along the Mediterranean shores, and to settle in selected spots; and that this process went on—not always peacefully, we may imagine—until the inferior occupiers of the land had been displaced, or absorbed and educated, and the superior culture was generally established—a matter probably of a few centuries. These immigrant conquerors, who brought with them new arts of life, and dispossessed the wandering hunters, introduced in western Europe the Neolithic Age. Whether a similar conquest or a more peaceful process of intellectual development produced the same result in other parts of the world remains to be discovered. In the earlier part of their history, at least, the Neolithic men continued to make and use strong hatchets, picks, flake-knives, etc., of flint and quartz, but the patterns were more serviceable; and they introduced an entirely new article in the stout axe, the chisel-like 'celt,' and other tools made of granite, jasper and other tough rocks, and formed by hammering, grinding, and then, often, polishing. This is the distinctive mark of the Neolithic period, but other distinctive innovations followed, of which the most important, socially, perhaps, was the making of pottery. They had the rudiments of agriculture, had domesticated the dog and ox and pig, refused to hunt horses for food but captured and tamed them; and to carry on these domestic industries they were settled in defensive houses and villages, an excellent idea of which may be had from the remains of their lacustrine towns (see LAKE-DWELLERS) in Switzerland and Italy. This article may fitly be closed by a comprehensive extract from Boyd Dawkins's standard work 'Early Man in Britain': "The arts of spinning, weaving, mining and pottery-making were known, and that of boat-building had advanced sufficiently far to allow of voyages being made from France to Britain, and from Britain to Ireland. Traffic was carried on by barter and stone axes were distributed over areas far away from those in which the stone was found. Tombs also were built, some of imposing grandeur, for the habitation of the dead in the after-world, in which the spirits were supposed to lead a life not very different from that of the living, and at which they were worshipped by the family or tribe, after the manner of the red Indians and many African peoples. . . . The neolithic civilization was long established, and underwent so little change, if any, in the lapse of ages that no traces of a change have been preserved to our times. Its duration varied in different countries, and it yielded place to a higher culture in Greece and Italy long before it passed away from central and northern Europe."

F., 'Modern Man and His Forerunners' (London 1917).

ERNEST INGERSOLL

STONE CIRCLES, circles of standing stones and of small boulders, found throughout Great Britain and in some places on the continents of Europe, Asia and Africa. See **STONES**, **STANDING**.

STONE COAL, a name used to some extent in the United States and in England for anthracite coal to distinguish it from soft coal or bituminous coal. On the continent of Europe it is more frequently used to distinguish the older (Carbonic) coals from the later Mesozoic and Cenozoic coals and lignites.

STONE-CROP, a plant, also called live-for-ever. See **SEDUM**.

STONE-CUTTING AND -DRESSING. This is the art of shaping, fitting, smoothing and finishing quarried stone, for use in masonry, foundations of monuments, arches, etc. (For the preliminary steps of taking out the stone see **QUARRYING**; **DRILL AND DRILLING**, the drill being one of the most important machines used in quarrying stone). Stone-cutting is more than a mechanical operation; it involves theoretical and geometrical calculations. The study of these is often termed **Stereotomy**. It involves some knowledge of architecture, and very exact calculations. Suppose that stones are required to be cut for an arch of 100 feet span and 25 feet rise. The exact curve and angle of each particular stone must be determined geometrically, and drawings made to guide the cutter. In the case of massive stone fronts for buildings, in which perhaps carvings occur, the design must be first perfected on paper, and sometimes models are made of more intricate parts. When dealing with angles the stone-cutter speaks of a batter of one in 10, meaning that there is a change of angle of one inch in width in 10 inches of length. Or he will specify a one in five rise, indicating the angle above the horizontal.

The primary tools of the stone-cutter are heavy hammers and chisels, the latter being operated with wooden mallets. By striking a stone a number of heavy blows with an edged hammer, along a given line, it will break approximately on that line. The more valuable stones, as imported marbles, are sawed, to avoid waste of material. For knocking off projections of stones from the quarry, a blunt double-faced hammer is used, of perhaps 20 to 30 pounds weight. Next, for roughly shaping, the face hammer may be employed, this tool having one blunt and one sharp face, and weighing ordinarily 20 to 25 pounds. The cavi, having

one blunt and one pyramidal point, is also useful for rough dressing, and is somewhat lighter than the face hammer. The mason's pick is straight, double pointed, and commonly 18 inches long. It is useful for rough-dressing soft stone. The mason's axe or pean-hammer has two cutting edges, of three to four inches wide. It is useful after the cavi, to prepare the stone for the patent hammer. The tooth-axe has a serrated double head and is not suited to very hard stone. The bush hammer has a head made of a series (as 36) of steel pyramidal points bound together; the points vary in size according to the work to be done. The Crandall and the patent hammer are forms of steel blades or chisels clamped together and used for finishing. Hand hammers, mallets and chisels complete the common tools of the mason for hand dressing. Chisels are named as tooth-chisels, splitting chisels and pitching chisels, the latter being used in forming a straight square edge on a stone. Short-handled, heavy mallets are employed with the chisels. In using a stone chisel, it has to be directed at such an angle as will break off the weaker part of the stone. The knack of this is soon learned, and the experienced stone-cutter will remove with each blow almost exactly what he calculates on doing. For rapid stone-cutting, pneumatic tools are now employed. The pneumatic hammer, operated like the familiar pneumatic rivetter, is very speedy in operation. Pneumatic plug drills and bushing tools are made and operated on the same principle, air pressure supplying force for the blow, and a spring returning the tool to position. Portable surfacing machines are used on large stones, an adjustable arm being swung over the stone, and aligned to the work. Any one of a variety of surfacing tools may be inserted in the tool carrier, and when the compressed air is turned on the tool pounds away at a fixed level under the guidance of the operator, who directs it over the entire surface requiring to be dressed. The stone saw is commonly employed for cutting up marble and sandstone. The cuts made are not quite smooth, and may be rubbed off with a slab and grit, operated by hand or power with water. Consult French, 'Stereotomy' (1906); Warren, 'Problems in Stone Cutting' (1911); Howe, 'Masonry' (1915).

STONE OF DESTINY. See **LIA-FAIL**.

STONE FERRY, Battle of. During the Revolutionary War an engagement took place here (20 June 1779) between the small entrenched force of British troops under Lieutenant-Colonel Maitland and a much larger body of the American forces under General Lincoln; the latter's attack was repulsed and Lincoln was obliged to withdraw as General Moultrie had failed to carry out the orders for preparedness and fresh forces came from the John's Island garrison of Britishers. The Americans sustained a loss of about 150 and the British about 130.

STONE-FLY, an aquatic neuropterous insect, much used as a bait in trout-fishing by anglers. These flies belong to the platypterous sub-order *Perlaria*, recognized by the hinder wings being of large size, and folded, while the tarsi are three-jointed, and the antennae or feelers are filamestary in nature. The abdo-

men is provided with a pair of long-jointed caudal appendages. The mandibles are rudimentary. These flies and their larvæ occur plentifully in the neighborhood of lakes and ponds. They are carnivorous, and the larvæ are aquatic.

STONE MOUNTAIN, a dome-shaped hill of granite in De Kalb County, Ga., rising about 700 feet above the surrounding level, and covering an area of about two square miles; also a town near by. The northern face of Stone Mountain is precipitous, its base presenting an almost vertical cliff 300 feet in height; but the other sides have a more gentle slope. The dome is everywhere naked rock, except where here and there a few hollows have permitted a little soil to accumulate, and some trees and shrubs to take root. Its visible bulk is estimated to contain seven and a half billions of cubic feet of dark granite, which is quarried from the northeastern foot. An electric road recently constructed from the neighboring town has made the rock a pleasure-resort, a path leading to its summit from the terminus. A plan has been made for the carving on the vertical northern face of the mountain of a series of gigantic figures representing scenes in the Civil War. This project would require a vast amount of time and money, and has been protested by many persons on the ground that its execution would detract from rather than enhance the interest of an extraordinary natural object.

STONE-PINE, a pine (*Pinus pinea*), common in the south of Italy, and often introduced into pictures of Italian landscapes. See **PINE**.

STONE RIVER, or MURFREESBORO, **Battle of**. After the battle of Perryville (q.v.) 7-8 Oct. 1862, and General Bragg's retreat from Kentucky into East Tennessee, Bragg was authorized by the Confederate government to make a movement into Middle Tennessee, and late in November had gathered his army at and near Murfreesboro, on Stone River, 33 miles southeast of Nashville. Wheeler's cavalry covered his front, its pickets within 10 miles of Nashville.

Gen. W. S. Rosecrans, who had succeeded General Buell in command of the Army of the Ohio, 27 October, made some changes in the organization of the army, henceforth to be known as the Army of the Cumberland; which was composed of the 14th Army corps. The corps was divided into three wings; the right wing, of three divisions, under Gen. A. McD. McCook, the centre of five divisions, under Gen. Geo. H. Thomas, and the left wing, three divisions, under Gen. T. L. Crittenden. On 26 December Rosecrans, with 56,000 men, advanced from Nashville in three columns, the right, under McCook, by the Nolensville pike, the centre, under Thomas, first on McCook's right by the Franklin pike and subsequently on his left; and the left, under Crittenden, by the Murfreesboro turnpike. Opposition was encountered from Wheeler's cavalry and Bragg's outposts at Nolensville, La Vergne and Stewart's Creek bridge; and there was some delay caused by rain and bad roads; but at night of the 29th Crittenden was close up to Murfreesboro, and under Rosecrans' orders to occupy the place he threw a brigade across Stone River, two

brigades were crossing the stream, and two divisions were under orders to follow, when the movement was suspended by Rosecrans, and the brigade recalled, after a sharp skirmish with a brigade of Bragg's troops. Thomas came up on Crittenden's right, but McCook was delayed until the next day, and after some severe fighting, in which he lost 135 killed and wounded, he took position on the right of Rosecrans' army, with his left, Sheridan's division, on the Wilkinson pike and with Davis's division on the right of Sheridan. At first R. W. Johnson's division was in reserve, but when McCook ascertained that the Confederate left overlapped him, Johnson was brought up on the right of Davis. Thomas rested his right, Negley's division, on the Wilkinson pike, connecting with Sheridan. Crittenden's left rested on Stone River, with his right across the Nashville and Murfreesboro pike connecting with Thomas.

General Wheeler had promptly informed General Bragg on the morning of the 26th that Rosecrans was on the march, upon which General Hardee's corps was ordered in from Triune, and Wheeler was directed to protect its flank, impede the Union advance and, when hard pressed, fall back upon the main body of the Confederate army, which was to give battle in front of Murfreesboro. Hardee's corps, consisting of the divisions of Breckinridge and Cleburne, with John K. Jackson's brigade as a reserve, made up Bragg's right wing; its right rested on the Lebanon pike, north of Murfreesboro, its left on the Nashville road. Wheeler's cavalry was on the right. Polk's corps—the divisions of Withers and Cheatham—was on Hardee's left, connecting with it on Stone River; McCown's division of E. Kirby Smith's corps, which at first was held in reserve east of the river, was ordered on the night of the 29th to cross over and extend Polk's left; so, on the night of the 30th, Hardee's corps was east of Stone River and Polk's corps and McCown's division west of it. The two armies bivouacked opposite each other; west of the river they were not over 500 yards apart. Rosecrans had on his rolls 56,000 men, of whom 43,400 were to become engaged; Bragg 51,000, of whom 37,700 were to be carried into action.

While Rosecrans was taking position on the 30th Wheeler's cavalry was raiding his rear. Wheeler, with seven regiments of cavalry and a part of a battery, started from Bragg's right, on the Lebanon pike, about midnight of the 29th, crossed Stone River at Jefferson, after daylight, and attacked Starkweather's brigade, by which, after a sharp fight, he was repulsed, with a loss to Starkweather of 122 men, most of them prisoners, but he captured and burned part of the brigade train. He then marched for La Vergne, picking up stragglers and burning wagons, and reaching La Vergne at noon of the 30th, attacked and captured the immense supply-train of McCook's command, which he burned, took and paroled over 700 prisoners and, pushing on to Rock Spring, attacked, captured and destroyed another large train. He then marched to Nolensville, capturing large trains, stores and arms, and about 300 prisoners, who were paroled; halted near Nolensville for a short rest; and at 2 A.M. of the 31st resumed his march and joined the left of the army, then engaged. He had made a complete circuit of the rear of Rosecrans' army, had taken and

paroled over 1,000 prisoners, and destroyed over \$1,000,000 worth of stores, leaving miles of road strewn with burning wagons. He brought back with him nearly 5,000 stand of small arms.

According to Rosecrans' plan of battle, McCook was to hold fast on the right and keep back Bragg's left in his front, while Thomas and the right division of Crittenden were to open the battle on the morning of the 31st with skirmishing, and to engage Bragg's centre and left as far as the river, and Van Cleve's and Wood's divisions of Crittenden's wing were to cross Stone River and attack Bragg's right, to drive it back through Murfreesboro, and into the open country toward Salem. Thomas was to take up the movement on Crittenden's right. The attack was to commence at 7 A.M.; Van Cleve's and Wood's divisions had been massed on the left; Van Cleve's skirmishers had crossed the stream, and one of his brigades had followed and formed line and the rest were in motion, when the roar of battle came up from the right, the movement on Bragg's right was abandoned, Van Cleve was recalled, and Rosecrans was obliged to yield his plan of battle to one laid down by Bragg.

Bragg had determined to attack and turn Rosecrans' right at daybreak, and for that purpose, leaving Breckinridge's division to hold the right against Rosecrans' left, Hardee was ordered to march Cleburne's division from the right to the left, take command of that and of McCown's division, and open the fight at daybreak by an attack upon McCook's right. Hardee's attack was to be followed up by Polk's divisions in succession to the right, the move to be made by a constant wheel to the right on Polk's flank on the river, as a pivot, the object being to force Rosecrans back on Stone River, gain the roads in his rear, and cut him off from his base of operations and supplies by the Nashville pike. On the night of the 30th Hardee led Cleburne's division to the left and placed it in rear of McCown. At daybreak McCown advanced and fell upon the right of R. W. Johnson's division while the men were preparing breakfast. The skirmishers had seen the advance and had resolutely opposed it, while the main line was preparing to meet the shock. The skirmish-line was driven in by the impetuous Confederate advance, and McCown, swinging to the right, overlapped Johnson's right, soon overcame the two brigades holding the first line, captured most of their artillery, and swept them from the field. McCown's first movement had diverged somewhat to the left, leaving an opening between his right and the left of Withers' division, into which Cleburne's division sprang, and then advanced on Davis' division, and it was severely engaged with Davis when Johnson gave way, upon which McCown turned one of his brigades upon Davis' flank. Davis changed front on his right, to meet McCown, made counter attacks upon Cleburne in his front, and repulsed some of Cleburne's fierce assaults, but was finally forced back with great loss, with a part of Sheridan's division on his left. Sheridan also changed front to meet attacks upon his flank; but after desperate fighting, making three successive stands and repulsing some furious assaults, he was obliged to fall back upon the divisions of Negley and Rousseau of Thomas' command, on the left of the Wilkinson pike; and upon those and Sheri-

dan, Polk's two divisions of Withers and Cheatham fell with great force, attacking them in front, left flank, and rear, causing them to fall back in rear of Crittenden's line. The entire right and centre of the Union line had now been driven back beyond the Wilkinson pike, and Rosecrans made heroic efforts to stem the tide setting against him and hold the Nashville pike, his only remaining connection with Nashville, and on which were all his trains. Everything was rallied on a new line covering this road, and Van Cleve's division of Crittenden's wing was brought up. There was another fierce struggle, but the Confederate attack was repulsed, with Rosecrans' right and centre thrown back at a right angle to its position of the morning, and with Bragg's line also at a right angle to his original line, the left of Rosecrans and the right of Bragg resting on Stone River. It was now past noon; Bragg held a large part of the field, with many prisoners, guns, wagons and ammunition, and the dead and wounded of both armies; but Rosecrans still held the road to Nashville. Bragg had made persistent efforts to crush the left of the Union line, where it rested near Stone River, and Polk's corps had been bloodily repulsed in several assaults on that part of the Union line. Another effort was now made. At 10 A.M. Bragg had ordered Breckinridge to send one brigade and, soon after, a second to reinforce Hardee; but when Bragg was informed that Rosecrans' left was crossing the river to attack Breckinridge the order was countermanded. It was ascertained that the information of an attack upon Breckinridge was incorrect; upon which Bragg ordered Breckinridge to send two brigades to report to Hardee, and soon after gave him a second order—to leave one brigade east of Stone River and march with the rest of his command to Hardee's support. When the brigades of Adams and Jackson crossed Stone River Hardee had been checked and thrown back, and the two brigades were sent to Polk, who was still assailing Rosecrans' left. The two brigades, the right of their line resting on Stone River, went forward, relieved part of Cheatham's, and became hotly engaged, but were driven back with great slaughter, some regiments losing more than half their men. As they were falling back Breckinridge came up with the brigades of Preston and Palmer, which were sent forward and speedily repulsed. Cannonading continued until nightfall, when, exhausted by a conflict of full 10 hours' duration, rarely surpassed for its continued intensity and the heavy losses sustained, both armies sank to rest.

While Bragg's infantry and artillery were breaking the Union lines and forcing them back, his cavalry under General Wharton, with part of McCown's infantry were engaged on Rosecrans' right and rear, inflicting losses in killed and wounded, capturing guns and wagons, and taking nearly 2,000 prisoners.

Rosecrans' losses during the day had been appalling, and when night came he was in some doubt whether to remain on the field. He says: "After a careful examination and free consultation with corps commanders, followed by a personal examination of the ground in rear as far as Overall's Creek, it was determined to await the enemy's attack in that position, to send for the provision train and order

up fresh supplies of ammunition, on the arrival of which, should the enemy not attack, offensive operations were to be resumed." There was a readjustment of the line, the left was drawn back, though still resting on Stone River, and the right and centre grasped more firmly the Nashville road. On the morning of 1 Jan. 1863 Bragg began to demonstrate with infantry and artillery, and again Wheeler's and Wharton's two brigades of cavalry sought the rear of the Union line. They attacked a large train near La Vergne, capturing part of it and a piece of artillery, and informed Bragg that heavy trains were moving toward Nashville, some loaded, and all the ambulances filled with wounded. Early in the morning Van Cleve's division, commanded by Col. S. Beatty, supported by Grose's brigade, was thrown across the river from the left, and formed line on a hill in front of Breckinridge, who had resumed his position on that side, on Bragg's right. During the morning of the 2d there was quiet along the lines except on Rosecrans' left, where there was some shelling, but there were indications that Bragg was meditating an attack upon Rosecrans' left, and preparations were made to meet it, Davis' division being ordered from the right to the left and some changes made on that flank. From his headquarters west of the river Bragg had seen that Polk's line could be enfiladed by artillery placed on the hill occupied by the right of Van Cleve's division, and after noon Breckinridge was ordered to take the hill and occupy it with his artillery. The two brigades that yet remained west of Stone River were returned to Breckinridge, and he was reinforced by 2,000 of Wharton's and Pegram's cavalry and some artillery. Breckinridge formed his division in two lines, two brigades in each, with two batteries of artillery in rear. He had, excluding the cavalry, which came too late to take an active part, about 4,500 men. The distance to be traversed was about 1,600 yards. At 4 p.m. the signal-gun was fired, and the four brigades advanced to the attack. After a severe fight the two right brigades of Van Cleve's division were broken and driven from the hill and toward the river. Bragg's order had been fully obeyed, but the Confederates, exultant with success, did not stop at the hill, but pursued the broken Union fragments, and as they neared the river a few of them crossed it. Major John Mendenhall, who had hurriedly massed 58 guns on a commanding position on the west bank of the river, opened fire with all the guns upon the somewhat massed column, the infantry added their fire, and Breckinridge's attack was repulsed. That part of Van Cleve's line that had not been driven across the river attacked the fleeing Confederates, a Union brigade, without orders, crossed the river in pursuit, and the Confederates were driven back to the position from which they had advanced with a loss of four guns and over 1,700 killed and wounded of the 4,500 engaged. It was night, and Davis' and Wood's divisions were sent across and intrenched on the hill that had been the point of contention. A cold and heavy rain-storm marked the 3d, and, fearing a rapid rise in the river, Rosecrans withdrew all his troops from the eastern side of it. No other movement was made on the lines, the day passed in comparative quiet, and at night Bragg,

under the erroneous impression that Rosecrans was receiving reinforcements, marched for Tullahoma, 36 miles distant. The 4th was occupied by Rosecrans in burying the dead, and on the 5th his army occupied Murfreesboro. The Union loss in the battle, including 53 killed and 259 wounded in minor engagements between Nashville and Stone River, was 1,730 killed, 7,802 wounded and 3,717 missing, an aggregate of 13,249. The Confederate loss was 1,294 killed, 7,945 wounded and about 2,200 missing. Consult 'Official Records' (Vol. XX); Van Horne, 'History of the Army of the Cumberland' (Vol. I, Cincinnati 1875); Stevenson, A. F., 'Battle of Stone River' (Boston 1884); The Century Company's 'Battles and Leaders of the Civil War' (Vol. III, New York 1887-88).

E. A. CARMAN.

STONE WORSHIP, a form of fetishism which has persisted in the religions of some cultivated races. The ancient Germans and Gauls paid reverence to stones: Saint Eligius (Eloi), bishop of Noyon, exhorts his Frisian converts against this practice: "Let no Christian presume to set lights or to say prayers (*reddere vota*) at fanes or rocks or fountains or trees;" and throughout the Middle Ages the Church never ceased to condemn the practice of addressing prayers or vows to stones—*votum votare ad lapidem vel ad quamlibet rem*. All the great nations of antiquity worshipped stones: at Phææ in Achaia, according to Pausanias, 30 square stones were worshipped; and he adds that in earliest times "rude stones, instead of images, received divine honors." Meteorites have ever been special objects of worship: such was the stone symbol of Diana at Ephesus, of the sun-god at Emesa in Syria, of Mars at Rome; such too was the Kaaba at Mecca. As stones are in India set up standing in groups as representing deities, Tylor conjectures that menhirs, cromlechs and dolmens may have had a like signification.

STONECHAT, a small and pretty European non-migratory bird (*Motacilla rubicola*), closely related to the American bluebird and the familiar English wheat ear. It is chiefly terrestrial in its habits.

STONEHAM, stôn'am, Mass., town in Middlesex County, on the Boston and Maine Railroad, 11 miles north of Boston. It was incorporated and became independent of the adjoining towns in 1725. It has several large manufacturing establishments, among which are boot and shoe factories, machine shops, box factory, tanneries and a furniture factory. It has a number of fine residences, six churches, 23 elementary school buildings, a high school and a public library. There are a national and a savings bank. Pop. about 7,090, of which 6,300 are in the borough proper.

STONEHENGE, stôn'hênj, a notable example of the ancient stone circles, situated in Salisbury Plain, Wiltshire, England, about seven miles north of Salisbury and within two miles of the town of Amesbury. The structure consists of two concentric circles of upright stones surrounding two concentric ellipses; the whole surrounded by a double earth wall and ditch, about 370 yards in circumference. There is an entrance at the northeast which proceeds in the

form of an avenue, guarded on each side by a wall and a ditch, for a distance of 594 yards, after which it divides, one branch going eastward up a hill, between two groups of burial mounds or barrows, and the other branch leading northwest to the cursus or race-course, about 300 yards distant. The outer earth-wall is 15 feet high, the ditch 30 feet wide and the avenue at the entrance 15 feet wide. The outer circle is about 105 feet in diameter and consisted when complete of 60 stones, 30 uprights and 30 horizontal imposts between them. The upright stones are about 16 feet high and six or seven feet thick. Of the original 60 there remain 32 stones, being 17 uprights in position, seven prostrate and eight imposts. At the avenue entrance there are 11 uprights remaining with five imposts. The uprights of the outer circle were placed about four feet apart, with the imposts fitted to them continuously at their top, each upright bearing a vertical peg at each side, into which fitted a mortise in the end of the horizontal impost. The imposts are on an average about 10 feet long, three and one-half feet wide and two feet eight inches deep. There is a space between the outer and the inner circles of from eight to nine feet forming a walk 300 feet in circumference. The number of uprights composing the inner circle has been stated variously, the different figures ranging from 40 to 60; there were no imposts in the inner circle and the height of the stones, judging from the 11 still standing, seems to have been about six feet. This circle, like the first, has an opening to the northeast, opposite the entrance. But unlike the outer circle, it is composed, not of hewn sandstone, but of smaller rocks, seemingly boulders brought from a distance. Within the inner circle and about the same distance from it as the outer circle stands the first oval, an incomplete oval, in the shape of a huge horse-shoe with its open end facing the entrance at the northeast. The first oval consists of five groups or trilithons, each trilithon being composed of two uprights with an impost at the top completely covering their upper edges. The five trilithons are thus independent and not connected by continuous imposts. Their size gradually rises from east to west, the largest being the grand central trilithon in the closed end of the ellipse and the smallest, about 16 feet high, those nearest the entrance. The height of the central trilithon, with impost, is 28 feet, the pillar stones being about 23 feet above ground, and the impost about four feet thick. Other dimensions of this trilithon are: Length of impost, 15 feet; breadth, four and one-half feet; breadth of uprights, seven and one-half feet; thickness, four feet. The other four trilithons stood two and two facing each other. Only two of these five groups are now perfect. One of the pillars of the central trilithon, fallen, is broken into three pieces; the impost though fallen is intact, and the remaining upright is nine feet out of the perpendicular. Of the two trilithons of the west side the one nearer the centre fell outward, entire, in 1797; though prostrate the stones are intact. The other trilithon on the west broke up at an earlier date; one of its pillar stones remains standing—the other and the impost lie at its foot, broken. The trilithons of this, the outer ellipse, are of

hewn sandstone like the stones in the exterior circle. Within this outer ellipse is a smaller one of the same shape, with the opening facing the northeast, but, like the inner circle, composed not of tool-dressed sandstone, but of blue-stone boulders, and, also like the inner circle, without imposts. The stones employed in the smaller ellipse are on an average about a foot to a foot and a half taller than those in the smaller circle; they are set at intervals of about five to six feet. Within the inner oval, at its upper end, in front of the central trilithon, is a slab of coarse-blue marble, 16 feet long, four feet broad and 20 inches thick. This is commonly spoken of as the altar stone. The cursus at the end of the western branch of the avenue of approach is a stretch of flat land, about one and three-fourths miles long and 110 yards across. It is bounded by parallel banks and ditches and is rectangular in shape, with a flat mound stretching across its eastern end. There is a smaller cursus a little to the north and barrows lie all around. Within the avenue of approach there is a large upright which has been nicknamed the Friar's Heel. It is 16 feet high and is supposed to be a bowing-stone.

The purpose of Stonehenge, its time of erection and the race or races which built it, will probably never be known with certainty. Despite the efforts of the numerous archæologists who have given it their attention, nothing in the nature of proof has been found for anyone of the various theories. It is generally accepted as an extraordinary development of the stone circles (q.v.) found throughout Great Britain and in parts of France and Scandinavia. For a long time these circles were known as Druidical Rings, and Stonehenge was regarded as probably the head temple of Druidical worship. This theory, however, has been discredited recently on account of the discovery that many other of these monuments, also supposed to be of Druidical origin, were of a sepulchral nature. The circular form of the monument has suggested to some writers that it was connected with a worship of the sun. By others it has been attributed to the Phœnicians, the Belgæ, the Saxons and the Danes. It has been called a martial court of justice—a battle ring for judicial combatants—a shrine to Buddha, a temple to serpent worship and a monument of victory. The theory most widely accepted is that it is a burial ground or a temple connected with burial ceremonies for some ancient people who inhabited at some time the greater part of Great Britain and who either emigrated from or to the shores of France and Scandinavia. The fact that Stonehenge is the centre of a region numerous in barrows, and that this is true of all the other great stone circles or standing stones seems to bear out the likelihood of its connection with the burial ceremony. Sir John Lubbock assigns its date as that of the Bronze Age, basing his beliefs on the character of the contents found in the surrounding barrows and upon the evidences of tool-work upon the stones of the outer circle and outer ellipse. This latter fact, however, is interpreted by others merely as an indication that the other portions of the structure are of much older date.

Stonehenge is first mentioned in the 9th cen-

ture by Hennius, who states that it was erected in the 5th century by Ambrosius, the last Briton king, aided by the magician Merlin, to commemorate the 460 Briton nobles who were treacherously murdered at that spot by Hengist, the Saxon. This legend is repeated by Henry of Monmouth in his *'Historia Britonum,'* in the 12th century, and then by numbers of the historians of the Middle Ages. The first history of Stonehenge, written by Inigo Jones, and published in 1655, speaks of the structure as a Roman temple and deprecates its demolition by the country-folk of the neighborhood, who removed portions of the fallen stones to build bridges, make mill-stones and for such like uses. (See *STONE CIRCLES*). Consult Barclay, *'Stonehenge and Its Earthworks'* (1895); Davies, *'Celtic Researches'* (1804) and *'Mythology of the Druids'* (1809); Gidley, *'Stonehenge Viewed in the Light of Ancient History,'* etc. (1877); Sir Henry James, *'Plans and Photographs of Stonehenge'* (1867); Lockyer, *'Stonehenge and Other British Stone Monuments Astronomically Considered'* (1906); Long, *'Stonehenge and its Barrows'* (1876); Sir John Lubbock, *'Prehistoric Times'* (ed. 1898); Flinders, Petrie, *'Stonehenge'* (1881); and Stukeley, William, *'Stonehenge and Abury'* (1840).

STONEMAN, stôn'man, George, American soldier: b. Busti, N. Y., 8 Aug. 1822; d. Buffalo, N. Y., 5 Sept. 1894. He was graduated at West Point in 1846, served on the Pacific Coast (1847-57), in 1855 was promoted captain, and until 1861 was on duty mainly in Texas. Early in 1861, while in command of Fort Brown in that State, he was ordered by General Twiggs to surrender to the Confederates. He refused, evacuated the fort, and with his men sailed by steamer to New York. In August 1861 he became brigadier-general of volunteers and chief of cavalry in the Army of the Potomac, and commanded the cavalry in the Peninsula Campaign of 1862 (q.v.), distinguishing himself at the battle of Williamsburg (q.v.). In November 1862 he was promoted major-general of volunteers, having already been placed in command of the Third corps, which he led at the battle of Fredericksburg. He led a cavalry raid toward Richmond during the Chancellorsville campaign. In April 1864 he took command of a cavalry corps in the Army of the Ohio, and during the Atlanta campaign made another notable raid (see *STONEMAN'S MACON RAID*). At Clinton, Ga., he was captured in July 1864, and for three months was kept a prisoner. In December 1864 he made his third important raid (see *STONEMAN'S RAID FROM EAST TENNESSEE INTO SOUTHWESTERN VIRGINIA*); and in the following March he entered upon still another of these remarkable incursions into Confederate territory. (See *STONEMAN'S RAID IN EAST TENNESSEE, SOUTHWEST VIRGINIA AND WESTERN NORTH CAROLINA*). In 1871, having received several brevets in the regular army, he retired from the service and settled in California, where for six years he served as a railroad commissioner, and from 1883 to 1887 was governor of the State, to which office he was elected by the Democratic party.

STONEMAN'S MACON RAID. When General Sherman was operating against Atlanta

he ordered all his available cavalry to prepare for a blow at the Macon Railroad, simultaneously with the movement of the Army of the Tennessee toward East Point. General Stoneman, with 5,000 cavalry, was to move by the left around Atlanta to McDonough, and Gen. E. M. McCook with two divisions of 3,500 men, by the right on Fayetteville; and on the night of 28 July 1864 Stoneman and McCook were to meet on the Macon Railroad, near Lovejoy's Station, and destroy it in the most effectual manner. On the morning of the 27th both columns started. McCook on the right, with 3,200 men and eight guns, marched down the west bank of the Chattahoochee, laid a pontoon-bridge near Riverton and crossed, and moving on Palmetto Station, on the West Point Railroad, tore up some two miles of the track, and went on to Fayetteville, where he captured about 250 prisoners, 500 wagons, which he burned, and 800 mules, a greater part of these he killed, and then pushed on to the Macon Railroad at Lovejoy's Station, about seven miles below Jonesboro, and 30 from Atlanta. He hoped here to meet Stoneman, but heard nothing of him, destroyed the depot, the railroad to some extent, burned army trains, and was prosecuting his work in the destruction of the road, when he was driven off it by a considerable Confederate force, and still hearing nothing from Stoneman, endeavored to return and recross the Chattahoochee by marching southwest, and had reached Newman, on the West Point Railroad, on the 30th, where he encountered an infantry brigade, coming from the south and at the same time was attacked in rear by Jackson's division of Wheeler's cavalry, soon reinforced by Wheeler himself with two additional brigades. McCook had several hard encounters, in some of which he was successful, but was forced to let loose his prisoners, about 400 in number, abandon his artillery and trains, and cut his way out, each brigade commander looking out for himself, and succeeded, with parts of his command, in reaching the Chattahoochee, which he crossed and marched to Marietta, with a total loss of about 600 men. Stoneman at the moment of starting had received Sherman's permission after the completion of his work at Lovejoy's, to march on Macon and Andersonville and release the thousands of Union prisoners, at these places. Marching on the morning of the 27th, he left Gerrard's division at Flat Rock, and with the brigades of Colonels Adams, Biddle and Capron, in all about 2,200 men, crossed the Ocmulgee River, near Covington, and made for the railroad running from Macon to Augusta, on which he destroyed a large number of engines and cars at Gordon and Griswoldville. A detachment went eastward and burned the bridge over the Ocoonee. Stoneman reunited his detachments near Macon, on the 30th, but the river was between him and the city, and he contented himself with shelling the place and then moved back toward Clinton. Meanwhile he had heard that the prisoners had been removed. General Iverson's cavalry division had been ordered by Wheeler to follow Stoneman, and was now upon him. On the morning of the 31st Stoneman, finding what he supposed to be a heavy Confederate force in his front, deployed a strong line of skirmishers, which soon developed the fact that Allen's brigade of Confederate

cavalry had passed around his flank and taken up a strong position directly across his line of retreat, while Armstrong's brigade, co-operating with Allen's, was closely menacing his left flank. Dismounting the men of one brigade he repeatedly charged the Confederates, but every charge was repulsed with heavy loss, and Armstrong followed by a charge upon his left flank. The Union line gave way and was with difficulty rallied and re-formed. By this time he was nearly surrounded, and as he mistakenly thought by a greatly superior force. Believing further resistance useless, he authorized his brigade commanders to cut their way out, while he, with a regiment and a section of artillery, held the enemy in check until the others got through, when he surrendered about 500 men. The greater part of Adams' brigade escaped and joined the army near Atlanta. Capron's brigade escaped, but was subsequently surprised and scattered, very few getting back to the Union lines. Consult 'Official Records,' (Vol. XXXVIII); Van Horne, 'History of the Army of the Cumberland,' (Vol. II, Cincinnati 1875); Sherman, W. T., 'Personal Memoirs' (Vol. II, New York 1875).

E. A. CARMAN.

STONEMAN'S RAID FROM EAST TENNESSEE INTO SOUTHWESTERN VIRGINIA. After the defeat of General Gillem's Union brigade at Russellville, Tenn. (q.v.), 14 Nov. 1864, General Thomas, commanding the Military Division of the Mississippi, of which East Tennessee was a part, ordered General Stoneman to concentrate his forces in Kentucky and advance from Lexington to Cumberland Gap to oppose General Breckinridge should he attempt to move into Kentucky, and to advance into East Tennessee and drive Breckinridge back into Virginia or North Carolina. Thomas' instructions were "to concentrate the largest possible force against Breckinridge, and either destroy his force or to drive it into Virginia and, if possible, destroy the salt-works at Saltville, and the railroad from the Tennessee line as far into Virginia as he could go without endangering his command." These instructions were repeated by Thomas on 6 December, when it was known that Breckinridge was on the retreat. By the 9th Stoneman had completed the organization of his command and was ready for operations in the field. He had a body of mounted troops, under General Burbridge, that had been doing duty in Kentucky, the Tennessee brigade of General Gillem, and some infantry and dismounted cavalry under General Ammen, in all a force of 8,000 men. The Fourth Tennessee and Third North Carolina (Union) regiments were sent to Paint Rock to hold the pass over the mountains into North Carolina, and Stoneman concentrated his command at Bean's Station on the 11th. Stoneman started from Bean's Station on the 12th, with Gillem's and Burbridge's commands of about 5,700 men, and Gillem, in advance, reached the north fork of the Holston River, opposite Kingston, during the night, crossed after a sharp engagement, and early in the morning of the 13th attacked and routed Duke's cavalry under Colonel Morgan, capturing Morgan and 80 of his men and his entire wagon train. During the day Burbridge pushed on to Bristol, to intercept General Vaughn, who had

been holding Greenville with some 1,200 men. Stoneman, with Gillem, joined Burbridge at Bristol early on the 14th, and fearing that Vaughn would pass in the night and join Breckinridge at Saltville or in the vicinity, Burbridge was pushed on to Abingdon, with instructions to send the 12th Kentucky cavalry forward to strike the railroad between Saltville and Wytheville to prevent the former place from being reinforced by troops from Lynchburg. The 12th Kentucky, after threatening Saltville, struck the railroad and cut off two trains that had brought Breckinridge with a battery and reinforcements from Wytheville, accomplishing its object. Stoneman now decided to push on to Wytheville, destroy that place and the salt-works on New River, and attend to the capture of Saltville on his return. He moved early on the 16th and Gillem overtook Vaughn at Marion, attacked and routed him, pursuing to Wytheville, capturing his trains, artillery and 198 men, and destroying the town. About midnight Burbridge's command was put on the road, and reached Mount Airy at daylight of the 17th, where Colonel Buckley's brigade was detached to destroy the lead-mines 25 or 30 miles beyond, in Wythe County, which was accomplished without loss. Having destroyed the railroad and bridges some distance beyond Wytheville, Stoneman now set out on his return to destroy the salt-works at Saltville, and on the 17th encountered Breckinridge in a strong position at Marion. He had moved out of Saltville with all the troops he could collect that had been operating in East Tennessee, and had not far from 2,000 men. With these he had proposed to follow Stoneman and attack his rear. He now stood in the path of his return. Burbridge, who was in the advance with two brigades, engaged him and called upon Stoneman for reinforcements; and Stoneman, riding forward, took the command in his own hands. Night soon came on, the troops had become disarranged, and a general attack was delayed until morning, when it opened with great spirit, Stoneman meeting with a stiff resistance and some loss, and making no headway. Buckley was supposed to be coming up in the afternoon, and Gillem, now up, was sent around Breckinridge's left, thus cutting him off from the salt-works. The skirmishing during the day was accompanied with considerable loss on both sides, and as soon as night set in Breckinridge finding himself cut off from Saltville, and nearly surrounded, withdrew by the road leading over the mountains into North Carolina and escaped. The 12th Ohio cavalry was sent in pursuit, capturing some abandoned wagons and caissons, and then returned; and that night Stoneman concentrated his command at Glade Springs. At daybreak of the 20th Stoneman advanced on Saltville in two columns, Burbridge to enter the place on the north, Gillem on the south. Gillem arrived first and waited for Burbridge, who was not in position, and night coming on and nothing yet accomplished, Colonel Stacy, with the 13th Tennessee cavalry, was ordered to make a detour to the left and dash into the town. Stacy carried out his orders to the letter. He dashed into the town, set part of his regiment to work in burning it and with the remainder charged the fortifications, held by 400 men under Colonel Preston, went over them, dispersing Preston's men, and

capturing two guns and a number of prisoners without the loss of a man. Stoneman says the charge "was a signal for a general stampede of the enemy, and by 11 o'clock in the night all the works were evacuated and in the possession of Colonel Stacy, and the town of Saltville was in flames." All day and night of the 21st was devoted to the destruction of the salt-works and all the machinery, and on the 22d Stoneman began his return march, Burbridge going by way of Big Sandy to Kentucky, and Gillem to Knoxville by Poor Valley and the west side of Holston River. Stoneman reports that he captured 34 officers and 845 men, 19 guns, 3,000 horses and mules, great quantities of ammunition, and from 50,000 to 100,000 bushels of salt, and that he destroyed the towns of Bristol, Abingdon, Wytheville and Saltville, 13 railroad trains, with engines attached, several trains without engines, all the depots of supplies in southwest Virginia, and railroad depots, foundries, mills, storehouses, turnpike and railroad bridges, but that the greatest loss inflicted was the destruction of the lead-works 17 miles from Wytheville and the salt-works at Saltville. A Confederate writer says: "The damage inflicted upon southwest Virginia by this Federal raid, in the destruction of railway and turnpike bridges, railway stations and warehouses, ironworks, woolen mills, leadworks and army supplies of all kinds was very injurious to the Confederacy, greatly crippling its defensive power in that region, and was also a serious blow to the Army of Northern Virginia by depriving it of supplies from that great storehouse of agricultural wealth." Consult 'Official Records' (Vol. XLV); Van Horne, 'History of the Army of the Cumberland' (Vol. II, Cincinnati 1875).

E. A. CARMAN.

STONEMAN'S RAID IN EAST TENNESSEE, SOUTHWEST VIRGINIA AND WESTERN NORTH CAROLINA. Early in February 1865, General Grant directed General Thomas to send an expedition under General Stoneman from East Tennessee to penetrate North Carolina and well down to Columbia, S. C., to destroy the enemy's railroads and military resources in that section and visit a portion of the State beyond the control or reach of Sherman's column, which had started on its march northward from Savannah. On the 27th Grant wrote that Stoneman was to repeat the raid of the previous fall, destroying the railroad as far toward Lynchburg as he could. As the movement was merely for the purpose of destruction, Stoneman was to avoid any heavy engagement. Stoneman's force, which was concentrated at Mossy Creek, East Tennessee, 22 March, consisted of the cavalry division of Gen. A. C. Gillem, three brigades of three regiments each, under Cols. W. J. Palmer, S. B. Brown and I. K. Miller, numbering about 6,000 men. It had now become known that Sherman had captured Columbia, S. C., and there were rumors that Lee's army would evacuate Petersburg and Richmond, with the possible intention of moving by way of Lynchburg to Knoxville; and Stoneman was, therefore, directed to move toward Lynchburg, give his first attention to the destruction of the railroad, and then sweep through western North Carolina. On the 24th Stoneman moved

to Morristown, and sent Miller's brigade to cut off a Confederate force between Jonesboro and Carter's Station, but the force escaped, and on the 26th Miller rejoined Stoneman, who had advanced to Jonesboro. All encumbrances were thrown aside, and with but four guns, and two ambulances to accompany the column, Stoneman left Jonesboro on the 26th and, crossing Iron Mountain, arrived at Boone, N. C., on the 28th, where he captured a body of homeguards, and the column was divided marching by two different routes across the Blue Ridge and through Wilkesboro, Jacksonville and Mount Airy, N. C., and Hillsville, Wytheville, Christianburg and Salem, Va., to within four miles of Lynchburg, destroying bridges and railroad track, capturing trains and prisoners, and causing the Confederates to abandon many guns. This was accomplished by 6 April, at which time Stoneman had possession of 90 miles of the Virginia Central Railroad, from Wytheville nearly to Lynchburg. The bridges over Roanoke and New rivers were destroyed, and on the 9th the entire command arrived at Danbury, N. C. Next day at Germantown, beyond Danbury, Palmer was detached and ordered to Salem, N. C., where he destroyed the extensive factories which were supplying the Confederate armies with clothing, then destroyed the railroad south of Greensboro, and also a part of it between that place and Danville, Va. The main column moved toward Salisbury, dispersing small bodies of the enemy, and bivouacking on the night of the 11th 12 miles north of that place. At midnight the march was resumed, and the South Yadkin River crossed, and at daybreak the Confederate pickets were driven in and across Grant's Creek two miles from Salisbury. The bridge across the creek was defended by 18 guns, under command of Col. J. C. Pemberton (formerly a lieutenant-general) and about 3,000 men, commanded by General Gardener. The flooring of the bridge had been taken up. Detachments were sent up and down the stream to cross and come in on the Confederate rear; and time being given for this, a charge was made on the bridge, the men went over on the stringers, and the Confederates were totally routed and pursued through Salisbury, Stoneman capturing the 18 guns, 1,364 prisoners, 10,000 stand of arms, and some wagons. At Salisbury an immense amount of public property was destroyed, and the railroad was wrecked for several miles south of the place. Having raided over 500 miles, destroying railroads, and capturing horses enough to refit his entire command, Stoneman concluded to take the prisoners and the captured artillery not destroyed to East Tennessee. He withdrew from Salisbury, on the 13th, and reached Lenoir on the 15th, where he turned over the command to General Gillem and, with a strong escort, conducted the artillery and prisoners to Tennessee. His instructions to Gillem were to scout on the east side of the Blue Ridge; to put Palmer's brigade at Lincoln to scout down the Catawba; Brown at Morgantown, to connect with Palmer on the Catawba; and Miller at Asheville, to open communication through to Greenville, Tenn. When Gillem, with the two brigades of Brown and Miller, reached the Catawba, two and one-half miles from Morgantown, the bridge was found

to be torn up, the ford blockaded, and the passage of the river disputed by General McCown with about 300 men and one gun. A flanking force was sent up the stream about two miles, crossed, and gained McCown's rear; the force in front attacked with artillery; and the infantry, crossing on the sleepers of the bridge, charged McCown and routed him, killing some of his men, and capturing his gun and about 50 prisoners. On the 19th Gillem moved toward Asheville, by way of Swannanoa Gap, reaching the gap on the 20th, which was found to be blockaded and defended by about 500 men with four guns. Leaving Miller to feint in front, Gillem, with the rest of his force, on the 21st, moved to Rutherford, 40 miles south of Swannanoa Gap, and at sundown on the 22d had passed the Blue Ridge at Howard's Gap, with but slight resistance and was in the enemy's rear. At daylight of the 23d his advance entered Hendersonville, where it was learned that the Confederates had retreated through the place. Pursuit was given and 70 men and four guns captured. The entire column then moved on Ashville, and at 3 P.M., when near the town, was met by a flag of truce, with a communication from General Martin, stating that he had received official notice of a truce between Generals Sherman and J. E. Johnston, and proposing a meeting next morning. At 11 P.M. an order was received from Sherman directing the command to move to Durham Station or Hillsboro. Being convinced that Sherman had given the order in the belief that the division was at or near Salisbury, and as it would have required a march of about 200 miles to reach Durham Station, and was but 60 to his base at Greenville, Tenn., Gillem determined to march to the latter place, and so informed General Martin, when he met him next morning, of whom he requested rations to make the march, and thus relieve him of the necessity of subsisting on the country, already impoverished. Martin furnished the rations, and on the 25th Gillem set his brigades in motion for East Tennessee. The raid was one of the most successful and destructive of the war. Gillem and Stoneman report the capture of 25 guns taken in action, and 21 that the Confederates were forced to abandon in southwestern Virginia; about 6,000 prisoners, and 17 battle-flags. Consult 'Official Records' (Vol. XLIX); Van Horne, 'History of the Army of the Cumberland' (Vol. II, Cincinnati 1875).

E. A. CARMAN.

STONEMAN'S VIRGINIA RAID. When General Hooker initiated the campaign finally resulting in the battle of Chancellorsville (q.v.), he ordered General Stoneman, commanding the cavalry corps of the Army of the Potomac, about 10,000 men and four batteries, to move quietly and rapidly up the left bank of the Rappahannock, on 13 April 1863, cross the river above the Orange and Alexandria Railroad, disperse Gen. Fitzhugh Lee's cavalry brigade at Culpeper Court House, push on to Gordonsville, and from there strike the Fredericksburg and Richmond Railroad at Saxton's Junction, destroying it with all its bridges and telegraph lines, thus severing General Lee's communications with Richmond. He was also directed to harass Lee's retreating troops that Hooker expected to defeat near Fredericksburg. Heavy

rains delayed both Hooker's plans and Stoneman's movement, and after Stoneman had crossed one brigade at Freeman's Ford the Rappahannock rose so rapidly and high that the brigade was recalled and crossed to the left bank of the river by swimming the horses. Stoneman now waited two weeks for Hooker's initiative and better weather. On 29 April, under modified orders to cross the river between Kelly's and Rappahannock Fords, and to send one column in the direction of Raccoon Ford and Louisa Court House, Stoneman again crossed the river, with the main body, at Kelly's Ford. General Averell, with three brigades and a battery, was to cross at Rappahannock Station, under instructions to push on through Culpeper Court House to Gordonsville and keep the enemy employed in that direction, while detachments from the main body were destroying the railroads north from Richmond. Stoneman had in all six brigades of cavalry, numbering about 8,000 men, with two batteries. Averell was dilatory in his movement, but soon ran against a regiment of Gen. W. H. F. Lee's brigade, driving it through Culpeper Court House and beyond the Rapidan, where on the morning of 2 May he received a message from Hooker that he did not understand what he was doing at Rapidan Station, and ordering him to rejoin the army at United States Ford. Averell immediately returned, and was relieved from command because he had failed to regard the instructions given him, and had contented himself with marching but 28 miles in three days with but an insignificant force opposing him.

With picked men and horses, in light marching order, not a wagon accompanying him, Stoneman pushed forward, with three brigades of 4,300 men and a battery of six guns; General Buford's regular brigade was sent to the left in detachments and, after skirmishing with small bodies of Confederate cavalry, reached the Rapidan at Raccoon Ford on the night of the 30th; Stoneman followed, the ford was crossed on the morning of 1 May, and at 2 o'clock on the morning of the 2d, after some opposition, and after marching through Orange Court House, Gregg's division of two brigades struck the Virginia Central Railroad about a mile from Louisa Court House and destroyed much of the railroad, and at day-break Colonel Kilpatrick, with his regiment, dashed into Louisa Court House, captured some supplies, and toward evening being attacked by some of W. H. F. Lee's cavalry, withdrew to Thompson's Cross-Roads, and joined his division, which during the day had marched by way of Yanceyville, and concentrated at the Cross-roads after night. Here during the night Stoneman gave orders for operations upon Lee's communications by separate parties led respectively by General D. McM. Gregg, Col. P. Wyndham, Colonel Kilpatrick, and Lieut.-Col. Hasbrouck Davis. At midnight, with a bright moon, the various detachments started, and all were on the road before 3 A.M. of the 3d.

Wyndham, with two regiments of about 400 men, pushed southward to Columbia on James River, at its junction with the Rivanna, driving before him a squadron of cavalry, and on the morning of the 3d he destroyed some canal-boats, bridges, and a large quantity of supplies and medical stores, and attempted to destroy the

stone aqueduct, by which the water of the canal was carried over the Rivanna; but hearing of the approach of W. H. F. Lee, he withdrew and rejoined Stoneman the same day, having marched 50 miles in 16 hours. He brought in 140 horses and mules, and was followed by Lee nearly to camp.

Kilpatrick marched, with one regiment, reached Hungary Station, on the Fredericksburg Railroad, at daylight of the 4th; destroyed the depot and part of the road, crossed to the Brook road, and went within two miles of Richmond, driving back a battery and some cavalry, and capturing about a dozen men within the fortifications of the city. Then he struck the railroad at Meadow bridge, over the Chickahominy, burned the bridge, ran a train of cars into the river, captured more prisoners and 60 wagons, crossed the Pamunkey and Mattaponi next day, swept through the country without opposition, though closely pursued by cavalry, and reached Gloucester Point on York River on the morning of the 7th, with a loss of 38 men. He reported that he captured and paroled over 300 men.

Lieutenant-Colonel Davis, with one regiment, moved along the banks of the South Anna to the Fredericksburg Railroad at Ashland, scattered a few cavalry bodies, captured an ambulance train with about 250 wounded from the field of Chancellorsville, whom he paroled, destroyed the road and other property in the vicinity, and pushed on to Hanover Station on the Virginia Central Railroad, burned the depot and other property, marched to Hanover Court House, and then to within seven miles of Richmond, when he changed direction to the left and started down the Peninsula for Williamsburg. At Tunstall's Station, near White House, he met and had an engagement with Confederate cavalry, infantry and artillery and, being repulsed in an attempt to break through, withdrew, moved to the left, crossed the Pamunkey and Mattaponi, and reached Gloucester Point, after a march of over 200 miles, with a loss of 35 officers and men.

Gregg and Buford meanwhile had been raiding in the neighborhood of the South Anna, closely watched by Wade Hampton and W. H. F. Lee. Buford's brigade was broken into detachments, and on the 4th one of these, under command of Capt. James E. Harrison, Fifth United States cavalry, was attacked at Fleming's Cross-Roads, by 800 men, under command of W. H. F. Lee. Harrison had less than 100 men, and after a hand-to-hand fight of about five minutes he retreated to Yanceyville with a loss of five killed and wounded, and two officers and 31 men captured. Lee fell back to Gordonsville, hearing by telegraph from Richmond that the enemy were everywhere. The whole of Stoneman's command, excepting the forces under Kilpatrick and Davis, was concentrated on the 5th at Yanceyville, on the South Anna. Stoneman says: "The six days having now expired, during which we were assured by the commanding general he would certainly communicate with us, and no communication having been received, no retreating enemy having been seen nor heard of, and no information as to the condition of things in the vicinity of Fredericksburg, except vague rumors of our defeat and capture, having been

attained; supplies for man and beast becoming scarce; having accomplished all that we were sent to perform, and having come to the conclusion that Colonels Kilpatrick and Davis, with their commands, had gone in the direction of Yorktown, I determined to make the best of our way back to the Army of the Potomac."

Knowing that the cavalry brigades of Lee and Wade Hampton were to the west of him, and that the withdrawal of Averell had exposed his flank and rear to an attack from them, he determined to send General Buford, with 650 men and picked horses, to threaten Gordonsville, and another force, under Captain Rodenbough, in the direction of Bowling Green, to threaten the enemy's communications and, under cover of night, with the main body, take the middle road through Tolersville, and crossing the North Anna near the Victoria Iron Works march to Orange Springs, where all were to rendezvous next day. Everything worked favorably. Buford marched to within two miles of Gordonsville, where he found infantry and artillery in position, awaiting his arrival, upon which he turned north, marched until nearly daylight, and halted on the north side of the North Anna, near Orange Springs, where at noon of the 6th he was joined by Stoneman, who had made a night march in a heavy storm. From Orange Springs Stoneman continued his march to Raccoon Ford, on the Rapidan, thence to Kelly's Ford, on the Rappahannock, which was crossed at daylight of the eighth by swimming the horses, and then to Bealeton.

The result of the raid was the capture of over 500 men and 460 horses and mules and the destruction of nearly 20 bridges and culverts, three trains of railroad cars, 122 wagons, several canal-boats, and a large amount of army supplies. The railroads had been cut in seven places, but these breaks, which General Lee considered as of small consequence, were soon repaired. As the chief object of the raid was the effectual destruction of Lee's communications with Richmond, which was not accomplished, it was considered a failure. The Union loss was five killed, 21 wounded and 163 missing. About 1,000 horses were broken down and abandoned, some being killed. There are no trustworthy records of Confederate losses in killed and wounded. Consult 'Official Records,' (Vol. XXV); the Century Company's 'Battles and Leaders of the Civil War' (Vol. III, New York 1887-88).

E. A. CARMAN.

STONES, STANDING, or STONE CIRCLES, are found in numbers throughout Great Britain, to a less extent in Norway and Sweden, and a few in France and northern India. The typical stone circle of Scotland, England and Ireland consists of rough, unhewn stone set up at comparatively equal distances in the form of a circle. These circles vary in size from a diameter of 20 feet to more than 100 feet, and are composed of stones of heights ranging from less than six feet to 19 feet, and of varying thicknesses. The stones are set up at distances of from five feet to six yards apart and the site of the circle is usually a level plain, although the gentle slope of a hill has sometimes been used. The stones used are often in the form

of huge loaf-shaped boulders set up on end and wedged in with smaller rocks at their bases; sometimes the standing stones are set into a slight excavation in the soil. In a number of the stone circles found in Scotland the space between two of the upright pillars, usually the two at the southwest side of the circle, is filled by a large flat rock set up on edge and extending from pillar to pillar. The location of this distinguishing feature at the southwest seems coincident with the general plan of structure and location of the supposed altar stone in the structure of Stonehenge (q.v.). Some of the stone circles contain a second smaller circle within them, which circle is often composed of stones larger than those in the outside circle; and some of the examples show a ditch around the circle of pillar stones, or else an earth wall. In either case whether it is ditch or wall, the entrance over or through it is invariably to the northeast. The ditches are in some instances as wide as 30 feet with a depth of six feet; the walls rarely exceed five or six feet in height, and the entrances over the ditches are usually half as wide as the ditch proper. In one notable instance, that of a small circle of large stones near the Great Circle of Stennis, in Orkney, Scotland, both the ditch and the rampart occur, the latter within the former, and the entire interior area of the circle is raised about three feet higher than the surrounding level.

Besides the circles of standing stones and great boulders, there are also found in the same territory and in Algeria, Syria and northern Arabia, continuous circles of smaller stones bedded in the ground or resting on the surface. Explorations of the interior area of these circles has established the fact that they were used for burying grounds, and from the nature of the contents, the burial urns and the implements found beside the graves, Sir John Lubbock has concluded that they belong to the Bronze Age. (See *STONEHENGE*). But it is to the circles of standing stones that the chief interest attaches; and while it has never been proven that these areas were intended for burying grounds, there seems to be sufficient reason for belief that they were connected with the burial rites of the people who erected them. This theory is borne out by the presence of burial mounds or barrows (known as cairns in Scotland and Ireland) in close proximity to all the larger circles. Indeed in some cases the cairns were surrounded by the circle of stones; as is seen in the great chambered cairn of New Grange in Ireland and in the smaller ones of Clava, near Inverness. Although it is more often the case, the contents of the cairns, particularly of the larger ones, do not always show interments of the Bronze Age. In this latter case there is no incinerary urn containing the deposits or over them, and the remains show that there has been no cremation. In like manner many of the stone circles, indeed the great majority of them, show no evidence of tool-work in their building, while the imposts of the outer circle and outer ellipse of Stonehenge give conclusive proof of it.

As a rule the cairns which covered the cremation interments of the Bronze Age are smaller than those of the preceding period, and the custom of placing the burnt bones in

a cavity in the soil, covered only by an inverted urn of clay, dispensed with the cairn altogether, while it retained the circle of standing stones as a visible mark or fence of the grave ground. In about 20 instances in which there has been systematic excavation of stone circles in Scotland, the examination of the interior space has disclosed burials of the Bronze Age mostly after cremation but occasionally unburnt. The cremated remains were deposited with cinerary urns placed either in an inverted position over the burnt bones or upright and containing the burnt bones, at the bottom of a shallow pit excavated in the subsoil. These cinerary urns exhibit the forms and ornamentation characteristic of the age of bronze. Sometimes the burials have been placed in cists of unhewn slabs of stone, covered by small cairns of loose stones, underneath the surface level; at other times the burnt bones of many burials have been found placed in shallow cavities excavated in the soil of the interior area of the circle near the bases of the upright stones. It seems from these circumstances that the common variety of stone circles, as found in Sootland, are cemeteries of the Bronze Age, and while, on the one hand, the difference in the size of the circles of Avebury and Stennis and in the structure and size of Stonehenge may point to a difference in purpose and use, on the other hand, the great size of the circle surrounding the chambered cairn at New Grange and the objects uncovered by the repair excavations at Stonehenge in 1901, seem to show that a great circle also was associated with a sepulchre.

The largest of the Scotch stone circles is that of Stennis, in Orkney. It has a circumference of 340 feet, enclosing an area of two and one-half acres, and is surrounded by a ditch 30 feet wide. It originally consisted of about 60 pillars, set about 17 feet apart, of an average height of about 13 feet. Of these 13 still stand and 10, though prostrate, are intact. The largest stone circle in England is that of Avebury, in Wiltshire, which consisted of a large outer circle of probably 1,000 stones of from 15 to 17 feet in height and 40 feet in circumference; this circle was about 1,000 feet in diameter and contained two smaller circles of 350 and 325 feet in diameter respectively. The inner circles each consisted of a double row of stones, a stone pillar 20 feet high occupied the centre of one, and a bowing-stone, or cromlech, that of the other. Surrounding the whole were a broad ditch and a high earth-wall, traversed by an avenue of approach which led toward the southeast for over 1,400 yards. This structure and Stonehenge are considered the most remarkable examples found in England of monuments of megalithic stones. In Norway and Sweden the few stone circles systematically explored have been found to be burial places of the Iron Age. They are usually simple circles composed of 8 to 13 stones; occasionally there are two concentric circles, one within the other, the inner circle being sometimes composed of small stones set close together in a ring. Sometimes there is a single pillar stone in the centre of the circle. As a rule they are not remarkable either for the size of the circles themselves or for the massive-

ness of the stones of which they are composed. Circles of standing stones are rare to the south of the Baltic. See bibliography under STONEHENGE. Consult also Dawkins, 'Early Man in Britain' (1880).

STONES OF VENICE. This work by John Ruskin, the first volume of which appeared in 1851 and the second in 1853, was the result of close study and labor in Italy and at home. It was a continuation and expansion of the theories he had already advocated in 'The Seven Lamps of Architecture' published in 1849. In that work he had sought to do for architecture what he had already achieved for painting in his 'Modern Painters' (q.v.)—to instil the sense of the indissoluble association of art with all other branches of human activity. The 'Stones of Venice' appeared contemporaneously with the 'Construction of Sheepfolds,' an eloquent plea for the reunion of Christian churches, and was as Carlyle wrote of it to the author, "a new Renaissance—a singular sign of the times—a sermon in stones." The book was beautifully illustrated with engraving from drawings by the author and some of the most prominent living artists and visualized an embodiment of the concrete idea which he sought to express, that the buildings and art of a people are the expression of their religion, their morality, their national aspirations and social habits.

STONEWARE is that kind of earthen ware (see CERAMICS) which is impervious to water and non-absorbent, almost non-porous, the whole substance of the paste being very silicious, either from the original nature of the clay or from a mixture with the clay of some natural silix such as flint. A simple test is that a broken fragment, if put to the tongue, will not seem to cling to its surface; whereas a broken flowerpot will cling tenaciously, this being caused by the rapid absorption of moisture by the porous substance. It is for this reason that stoneware is used for acid containers, bottles, vinegar jugs and all such common purposes, and also for larger and more decorative vessels in countries and in times where it is customary to use earthenware vessels instead of glass or metal at least to a great extent. Thus in the Rhine towns and northwestern Germany during the 14th and following centuries a very elaborate series of cans, jugs and flagons of all sizes from a pint to three or four gallons, were made and decorated by simple impressions from metal or wooden dies impressed upon the surface before firing; the pattern being afterward more or less emphasized by a thin glazing of blue applied in parts. The glaze of stoneware in the usual sense is no more a separate substance than that of Greek vases; it is a mere modifying of the surface generally by some vaporized ingredient which is absorbed during the actual process of firing. Thus the most common glaze, called salt-glaze, is generally understood to be produced by throwing into the furnace rough salt, which is vaporized and leaves the soda in its composition on the surface of the stoneware in the form of a slight, glassy film. The stoneware would not need this to be sufficiently resistant against water, wine or the like, but some acids would attack the stoneware, against which the glaze is a sufficient protection.

These decorative wares have been known to the collectors, and in museums and in treatises on Ceramics under the general name of grès de Flandre, as if they were of Flemish make, but this term is now replaced by such terms as Cologne Ware, German Stoneware and the like. In modern times stoneware has not been generally used for decorative purposes; but recent experiments in the national manufactory of porcelain at Sèvres in France have led to the invention or adoption of many brilliant colored enamels which can be applied to stoneware without in the least diminishing its value as a durable and weatherproof material; and in this way a whole class of architectural ceramic wares has been made practicable. Magnificent specimens of these wares—even to the extent of huge friezes containing many figures, were on exhibition at Paris in 1900 and any future attempts at decorative architecture will have to include the consideration of these new means of brilliant adornment in color and in form. See POTTERY.

STONINGTON, stō'ning-tōn, Conn., town, New London County, on Long Island Sound and on the New York, New Haven and Hartford Railroad, about 10 miles east of New London and 40 miles southwest of Providence, R. I. It comprises the borough of Stonington and the villages of Mystic, Old Mystic and Pawcatuck. There is a good harbor. The principal industries are agriculture and the manufacture of machinery, printing presses, woolen goods, velvet goods, thread, fertilizers, cotton and silk goods, etc. The first permanent settlement in Stonington was made by William Chesebrough of Plymouth in 1649. In 1658 it was chartered by Massachusetts as Southerntown; passed to Connecticut in 1662, and in 1665 was named Mystic, and Stonington the year following. It was attacked by Sir James Wallace in the frigate *Rose* in 1775 and in 1814 was bombarded four days by Admiral Hardy. Sealing and whaling were for many years among the town's most flourishing industries. The area of the town is 25,222 acres. It is reached by steamboat from Watch Hill in the summer season. Government is vested in a warden and burgesses as an official board. Pop. 9,477. Consult Palmer, 'Stonington by the Sea' (Stonington 1913) and Wheeler, 'History of the Town of Stonington from 1649-1900' (New London 1900).

STONY CREEK, Battle of, in the War of 1812. After the capture of Fort George (q.v.) General Dearborn sent Gens. William H. Winder (q.v.) and John Chandler with 1,300 troops in pursuit of the retreating British under Gen. John Vincent. Chandler marched to Stony Creek, within 10 miles of Vincent's position at Hamilton. Learning of the American advance, Vincent with 750 troops attacked on the morning of 6 June 1813 and might have captured the whole force of Americans had not the Indians accompanying him raised the usual war-whoop, thus warning the Americans of the attack. In the confusion that followed, both Chandler and Winder walked into the midst of the British troops and were captured, and Vincent, too, lost his way, being found the next day without sword or hat. The British loss was 23 killed, 134 prisoners and 55 missing; the Americans lost 17 killed, 38

wounded and 100 missing. Had the Americans pursued they might have captured the main body of the enemy, but abandoning baggage and leaving the dead unburied they retired 10 miles up Forty Mile Creek and thence went to Fort George arriving 8 June and remaining inactive until the battle of Beaver Dams (q.v.). Consult Armstrong, John, 'Notices of the War of 1812' (Vol. I, pp. 134-141); 'American State Papers, Military Affairs' (Vol. I, pp. 445-448); Brackenridge, H. M., 'History of the Late War' (pp. 117-118); Brannan 'Official Letters' (pp. 165-171); Lessing, 'War of 1812' (pp. 602-604); Wiley and Rines, 'The United States' (Vol. V, pp. 406-407).

STONY POINT, N. Y., town in Rockland County, on the west bank of the Hudson, and on the New Jersey and New York, the New York, Ohio and Western and the West Shore railroads, 35 miles north of New York City. At this point is the rocky promontory from which the town derives its name, which was strongly fortified during the Revolutionary War by the British. In 1779 the Americans had begun to fortify the place, but were forced to abandon it by the British under Clinton, who then completed the fortifications. The only land approach was across a marsh which was covered by water at high tide and was defended by a double line of abattis and picket stations. Washington had determined on a recapture of Stony Point and for this purpose organized a body of picked troops known as the Corps of Light Infantry and placed Gen. Anthony Wayne (popularly called "Mad Anthony") in command. Wayne carefully reconnoitered the place and decided for a night attack and surprise, which was carefully planned by Washington. In accordance with this plan, Wayne brought his men as near Stony Point as possible and by 8 p.m., 15 July, camped about a mile from the fort. Here he divided his force into columns, and about 11:30 commenced the march against the fort; when the marsh was reached, one column under Wayne turned to the south to cross the marsh, the other to the north. By the time the Americans had crossed the morass, the British were thoroughly aroused, and opened fire upon both columns. The Americans did not fire but charged with the bayonet so impetuously that the enemy were quickly driven from the outer abattis into the fort, where they were obliged to surrender; the two American columns reached the fort almost at the same time. Wayne was wounded in the head during the charge, and was carried into the fort but the wound proved slight. The whole British garrison of over 540 were taken prisoners; the Americans lost only 15 killed, the British 63. The Americans were not able to hold the place, but destroyed the fortifications, and it was reoccupied for a time by the British who, however, abandoned it in October. The immediate effect of the victory was to encourage the Continental army, and increase the confidence and zeal of the people. The site of the fortifications was acquired as a public park by New York State in 1897. The population of the village is less than 1,000, but the town's population is about 4,000. Consult Johnston, 'The Storming of Stony Point' (New York 1900).

STONYHURST COLLEGE, England, a Roman Catholic institution 10 miles north of Blackburn, Lancashire. The college was originally founded at Saint Omer in Flanders in 1592, but in 1794 was transferred to England. It is affiliated to the University of London, and provides a school course of instruction for boys and a university course for young men. Attached to it is a good observatory, an excellent library of 40,000 volumes, museums, etc. Several wellknown men have been educated here. The series of 'Stonyhurst Philosophical Manuals' by the Jesuit professors in the philosophical department of the college represents an able and notable attempt to revive the scholastic philosophy as expounded by Saint Thomas, and adapt it to modern thought.

STOOP, in architecture, an uncovered platform at the entrance to a house or other building, raised to the height of the door-sill and approached by a flight of steps, the same width as the stoop. The word is Dutch, having its origin in New York in Colonial days. It is frequently used incorrectly for porch or veranda.

STOPPAGE IN TRANSITU, in law, is the exercise of a right allowed by law to a seller to stop the delivery of goods purchased by a buyer who has become bankrupt while the goods are in the hands of a carrier or middleman for transmission. Under the laws of England it is not necessary that the vendee should have been judicially declared bankrupt or insolvent; mere inability to pay his debts as they become due constitutes the insolvency contemplated by the law. Of course the burden of proof rests on the seller to establish the fact of insolvency or bankruptcy in case it is denied. Stoppage in transitu is not held to cancel the transaction, but only to place the goods under lien of the seller for the price. The transitu, during which goods are liable to stoppage, is terminated by actual or constructive delivery to the buyer or his agent. A common carrier is not considered the agent of the buyer, although employed by him for the transmission of the goods; but if goods are delivered at a shipping port to a buyer's agent for transshipment, the transitu is at an end and cannot be renewed when they are redelivered to a common carrier. Although the buyer is the charterer for the voyage of the ship in which the goods are carried they are not held to be delivered to him until the delivery is completed in the usual manner at the close of the voyage; but if he has hired the ship for a period it will be considered as his premises and the delivery will be complete. The law of the United States in relation to this subject is virtually the same as that of England.

STORER, Bellamy, American diplomat: b. Cincinnati, 28 Aug. 1847. He was graduated from Harvard in 1867, and from Cincinnati Law School in 1869. He practised law in Cincinnati; was a member of Congress, 1891-95; United States Minister to Belgium, 1897-99; to Spain, 1899-1902; United States Ambassador to Austria-Hungary, 1902-06, when a controversy with President Roosevelt over ultra-diplomatic activities led to his resignation. Consult Storer,

B., 'Letter to the President and the Members of his Cabinet' (1906).

STORER, David Humphreys, American physician and naturalist: b. Portland, Me., 26 March 1804; d. Boston, Mass., 1891. He was graduated at Bowdoin College in 1822, studied medicine at Harvard Medical School, then started to practice (1825) in Boston and continued till 1888. He was called to the chair of obstetrics and medical jurisprudence in 1854, in Harvard Medical School, becoming dean from 1855 to 1864. In 1866 he became president of the American Medical Association. He wrote 'Report on the Ichthyology and Herpetology of Massachusetts' (1839); 'Synopsis of the Fishes of North America' (1846), long the standard on this subject. In 1876 he was awarded the degree LL.D., by Bowdoin.

STORER, Francis Humphreys, American agricultural chemist: b. Boston, Mass., 27 March 1832; d. 1914. He was son of David H. (q.v.). He studied chemistry under Prof. J. P. Cooke, becoming his assistant in 1851, and was graduated at Harvard in 1855 after returning from an exploring expedition of the United States to the North Pacific. He next went to Europe and studied under Bunsen at Heidelberg, Richter at Freiberg, Stoeckhardt at Tharund, and Emil Kopp in Paris. On his return (1857) he became chemist to the Boston Gas Light Company while working in a private laboratory. In 1865 he became professor of general and industrial chemistry at the Massachusetts Institute of Technology. He was appointed, in 1870, professor of agricultural chemistry at Harvard University and became (1871) dean of the Bussey Institution. In conjunction with Cyrus M. Warren he made notable researches upon hydrocarbons. While at the Massachusetts Institute of Technology he developed, in collaboration with Charles W. Eliot, a system of teaching applied arts chemistry; together they published 'Manual of Inorganic Chemistry' (1868), setting forth their advanced method of training, which became very popular. Other valuable works were 'A Dictionary of Solubilities of Chemical Substances' (Cambridge 1864); 'Manual of Qualitative Chemical Analysis' (1868; 17th ed. 1893); 'A Cyclopædia of Quantitative Analysis' (1870-73); 'Elementary Manual of Chemistry' (1894); 'Agriculture in Some of its Relations with Chemistry' (3 vols. 1897); 'Manual of Qualitative Analysis' (1899).

STOREY, George Adolphus, English artist and author: b. London, 7 Jan. 1834. He first exhibited at the Royal Academy in 1852. In 1863 he was in Spain, painting portraits at Madrid. Among his pictures are 'A Royal Challenge' (1865); 'After You' (1867); 'The Shy Pupil' (1868); 'The Old Soldier' (1869); 'The Duet' and 'Only a Rabbit' (1870); 'Rosy Cheeks' and 'Lessons' (1871); 'Little Butter-Cups' (1872); 'Caught' (1875); 'A Dancing Lesson' (1876); 'The Ivory Door' (1881); 'Coracles on the Dee' (1882); 'The Connoisseur' (1883); 'First Practice' (1894); 'Rival Minstrels' and 'Coming Events' (1895); 'A Love Stratagem' (1896); 'A Fair Musician' (1897); 'Daughter of the Regiment' (1897); 'In Evening Shade' (1898); 'The Lost Labour of the Danaïdes'; 'Philomel' (1900);

'The Love Letter' (1901); 'A Love Sonnet'; 'Miss Reynolds' (1902); 'Pluto's Messenger' (1904); 'Venus Lamenting the Death of Adonis'; 'Griselda' (1905); 'Leda,' 'Pamela,' etc. (1906); 'Mrs. E. W. Meyerstein' (1907); 'Phryne' (1908); 'Circe,' 'Pan and Syrinx,' and 'Phyllis Meyerstein' (1909); 'My Mother's Portrait,' purchased for the National Gallery of British Art; 'My Father's Portrait' (1874); 'Lady in Furs'; 'Miss Gladys Storey' (1912); 'Her First Letter' (1913); 'A Young Painter,' 'Edward Cressy'; 'Armida in the Enchanted Wood' (1914); 'Viola' (diploma work), 'Diana' (1915). He is author of 'Sketches from Memory' (1899); 'Theory and Practice of Perspective' (1910).

STOREY, Moorfield, American lawyer: b. Roxbury, Mass., 19 March 1845. He was graduated from Harvard University in 1866 and from the Harvard Law School three years later. He was private secretary to Charles Sumner 1867-69, and from 1873-79 was editor of the *American Law Review*. He was active in the "Mugwump" movement in 1884 and was president of the American Bar Association in 1896. He has published 'Life of Charles Sumner' (1900), and a 'Memoir' of E. R. Hoar (1911).

STORKS, a family (*Ciconiidae*) of wading-birds of the order *Herodiones*. In this family the bill is very stout at the base, longer than the head, usually straight but occasionally curved either up or down. The nostrils are remarkable in being entirely unprotected either by a scale or bristles; they are placed close to the base of the bill and perforate its horny sheath directly, not being even sunk in a groove. The hallux is placed on a level with the other toes which are either moderately or considerably elongated and terminate in a more or less flat, broad claw. The general aspect of these birds is somewhat heron-like but they lack all of the grace of those birds, being of rather heavy build and clumsy action. To this family belong the true storks, the jabirus and the wood ibises, the latter being quite distinct from the true ibises. True storks form the subfamily *Ciconinae* and, with the exception of the closely related American jabirus, are confined to the warmer parts of the Old World, where about six genera occur. The white stork (*Ciconia alba*), which during some portion of the year is found in most parts of Europe, Asia and Africa, is the celebrated bird of German and Dutch story and folklore, and familiar from the pictures in children's Christmas books of German manufacture. In its domesticity and love of human habitations as nesting-sites it departs widely from the solitary, retiring habit of most of its kindred; but in other respects it is thoroughly a stork, feeding upon frogs, small fishes, mice and insects, which are captured in the marshes and meadows; sleeping during the heat of the day often with one foot drawn up and the bill lying on the breast; becoming active at dusk and in the cool of the morning; voiceless but producing a clattering noise with its bill; during the mating season indulging in dances and other queer stiff-legged antics; and on the approach of cold weather migrating to Africa. They fly in pairs or small flocks at a great height and with their long legs stretched out straight behind. A

stork's nest on the house-top is the best of good omens and as the birds are undisturbed they return year after year to add to the huge structure of sticks and raise another callow brood. Other species of the same genus inhabit Europe, Asia and Africa, but they breed on rocky cliffs or tall trees and shun human habitations. The adjutant (*Leptoptilus dubius*) of India is another semi-domesticated species which acts as a scavenger and feeds largely upon carrion. A very peculiar Indian stork is the open-bill (q.v.) in which the mandibles do not completely close. Its food consists largely of mussels. But two species (*Dissura maguari* and *Mycteria americana*) inhabit America, the last only, the jabiru, entering occasionally the southernmost United States. It is a large bird, standing more than four feet high, with a huge, massive bill more than a foot long, the head and neck bare and black except for a bright red zone on the lower part of the latter; the plumage is entirely white. The young are largely grayish. Along the seacoast and about the mouths of some of the rivers of tropical South America this bird is very abundant. Besides capturing living reptiles, frogs, etc., it feeds upon carrion and has a curious habit of probing the mud with its bill in search of worms and larvæ. Its nest, a platform of sticks, is built in tall trees and two dull green eggs more than three inches long are laid. When angered or excited the crop is inflated beneath the red skin of the throat which swells out like a huge ball of a most threatening aspect. The wood ibises form the subfamily *Tantalinae*, distinguished from the true storks chiefly by the strongly decurved bill and longer claws. *Tantalus* is generally considered to be the only genus, with species in tropical Africa, India and the Malayan Islands, and the American *T. loculator* which inhabits the entire South American continent and the southern United States, occasionally straying northward to Pennsylvania and New York. Except that it is gregarious, especially when breeding, its habits are stork-like. In the Southern States the wood ibis is resident in thickly wooded swamps, along the seashore, rivers and bayous where it is extremely abundant in many places. In Florida, however, it is said to be more solitary. When feeding it rakes the bottom with its hooked bill and captures the small fishes, worms, mollusks and crustaceans thus disturbed; in fresh water it captures especially crayfish and batrachians, and on land snakes, lizards and rats. The two or three eggs are dull white. The stork is the omen of births, and "to receive a visit from the stork" means to have a new baby in the family. Consult 'Newton Dictionary of Birds' (London 1896); Gubernates, 'Zoological Mythology' (New York 1872); Baird, Brewer and Ridgway, 'North American Water Birds' (Vol. 1, Boston 1884).

STORM, störm', Theodore, German novelist, poet and short story writer: b. Husum, a seaport and manufacturing town of Schleswig, on the coast of the North Sea, 14 Sept. 1817; d. Hademarschen, 4 July 1888. He studied law at Kiel and Berlin and practised his profession in his native town. On account of his strong German sympathies in the Schleswig-Holstein question he was forced to leave the country and was a political exile for 10 years (1854-64). When

the disputed territory passed under the dominion of Prussia in the latter year he was permitted to return and was rewarded with several judicial positions under the Prussian government for his faithfulness to the German cause, and he was finally retired on a government pension in 1880. His most popular story is 'Immensee'; but it is only one of half a hundred which were received with satisfaction by the German reading public. In this story he recalls, in a strangely vivid, poetical, realistic, yet dreamy, fanciful manner, the scenes of his early life. Almost all his stories and poems are touched with the same quiet sadness as that which characterizes 'Immensee.' This loneliness and melancholy surround most of the people about whom he writes. Yet through this strange loneliness there is ever in evidence an engaging warmth of heart and tender sentiment expressed in sweet and graceful language. Everywhere we feel, in the stories, novels and poems of Theodore Storm, that he expresses much more by suggestion than he actually says; and this characteristic forms one of the chief charms of his works. Storm may be called the prose Longfellow of Germany. See IMMENSEE.

STORM, The ('Groza'). In this tragedy, which appeared in 1860, Ostrovski has given the most vivid picture in literature of the frightful consequences of domestic despotism, such as formed the foundation of the lives of the Moscow merchant class. The old widow Kabanikha believes in the rule of terror and cannot understand her son's sentiment that his wife should not live in fear of him. Catherine, his wife, who is the heroine of the play, has by the critic Dobrolyubov been denominated "a ray of light in a world of darkness." She is one of the most touching characters in any literature. Warmhearted, profoundly religious, her nature is chilled in her home surroundings by the hostility of her stern mother-in-law and the indifference of her profligate husband. She begs him not to go on a journey, not to rob her of her soul's peace. During his absence she is easily captivated by the urbane Boris, and she falls. Upon her husband's premature return a raging storm evokes in her mingled feelings of superstition and remorse, and she confesses to her husband. When she hears that Boris is forced to leave for a long journey she, in a sense comparable to the finest scenes in Goethe's 'Faust,' bids him good-bye and then commits suicide by leaping into the river. The positive characters in the play are Catherine's family, among whom she had been brought up in love, and the autodidact Kuligin, who gives expression to Ostrovski's humane sentiments in some such way as did the chorus in the ancient Greek tragedy. In Russia this drama has maintained itself on the repertoire until the present time, but it has not met with success abroad, on account of the great objectivity of the characters and the absence of climaxes and melodramatic situations. It is to be found in an English translation by Constance Garnett (London 1899 and Boston 1907).

LEO WIENER.

STORM KING, or **BUTTER HILL** (called by the early Dutch *The Klinkenberg*, which means "Echo Mount"), one of the highest peaks of the Highlands on the west

bank of the Hudson, in Orange County, N. Y. It was also called *Boterberg* (Butter Mountain) by the Dutch. It is a rounded mass (1,530 feet high), made more conspicuous by being on the river's bank. The village of Cornwall is near by. The peak stands like a "storm king" at the northern "Gate of the Highlands," as a protection against the fierce storms of the north.

STORM-PETREL. See *MOTHER CAREY'S CHICKEN*.

STORM AND WEATHER SIGNALS. See *METEOROLOGY*; *WEATHER BUREAU*.

STORNOWAY, stôr'nô-wâ, Scotland, a seaport in Ross and Cromarty County, on the east coast of the island of Lewis, Outer Hebrides. The principal buildings are the courthouse, assembly-rooms, public library, customs house, drill-hall, industrial and grammar schools. There is a naval reserve station, a good harbor with quays and wharves, and a ship-building yard with patent slip. The herring and whitefish fisheries are valuable. The town has a population of about 4,000, and the parish of about 14,000.

STORRS, stôrz, **Richard Salter**, American Congregational clergyman: b. Braintree, Mass., 21 Aug. 1821; d. 5 June 1900. He was descended from a long line of ministers; was graduated at Amherst in 1839, and at the Andover Theological Seminary in 1845. He preached for a year in Brookline, Mass.; and in 1846 became minister of the Church of the Pilgrims, Brooklyn, N. Y., continuing in that pastorate until his death. He reached a commanding position among the leading preachers of his time, and added new meaning and dignity to the title of pulpit orator, which by eminence he bore, although his oratory was free from limitations of a professional character, being effective through its intellectual and moral qualities and its masterful delivery, whatever the subject or the occasion might be. He was also a scholar and writer of much distinction, and contributed articles on various subjects to many publications. From 1848 to 1861 he was one of the editors of the *Independent*. He also published 'The Graham Lectures on the Wisdom, Power and Goodness of God, as Manifested in the Constitution of the Human Soul' (1856); 'The Conditions of Success in Preaching Without Notes' (1875); 'The Divine Origin of Christianity Indicated by his Historical Effects' (1884); 'Bernard of Clairvaux' (1892); 'Forty Years of Pastoral Life'; and also many religious, historical and literary discourses of varied interest. From 1887 to 1897 he was president of the American Board of Commissioners for Foreign Missions. Consult Storrs, Charles, 'The Storrs Family' (New York 1886).

STORRS, **William Lucius**, American jurist and congressman: b. Middletown, Conn., 25 March 1795; d. Hartford, Conn., 25 June 1861. He was graduated (1814) at Yale College and admitted (1817) to the New York bar, soon returning to practice at Middletown. He was elected member of the State assembly (1827-29) and again in 1834, when he became speaker the last term. From 1829-1833 he was member of Congress for Connecticut, and again in 1839-41, when he resigned to become

judge of the Supreme Court of Connecticut, serving till 1856. From the latter date till his death he was chief justice of the Supreme Court of Connecticut. From 1846-47 he was professor of law in Yale College. Western Reserve conferred the degree of LL.D. on him in 1846. His decisions may be found in the 'Connecticut Reports.'

STORTHING, stôr'ting, the parliament or legislative assembly of Norway. It is elected triennially, and holds annual sessions. See *NORWAY*.

STORY, **George Henry**, American artist: b. New Haven, Conn., 22 Jan. 1835. After serving three years' apprenticeship to a wood carver he studied under Charles Hines for a like period. He next spent a year in Europe, after which he went to Portland, Me., where (1859) he received the State medal. In 1863 he settled in New York, where he has painted many notable portraits and genre pictures. At the Philadelphia Centennial Exposition he was awarded a medal. From 1889-96 he was curator of the department of paintings at the Metropolitan Museum of Art, New York, becoming acting director 1904-05, and has been curator emeritus since 1906. He received A.N.A. diploma in 1875.

STORY, **Joseph**, American jurist: b. Marblehead, Mass., 18 Sept. 1779; d. Cambridge, Mass., 10 Sept. 1845. He was graduated from Harvard in 1798, and afterward studied law. In 1808 he entered Congress, in 1811 became speaker of the Massachusetts State legislature, and soon after was appointed a judge of the United States Supreme Court. In 1829 he became first Dane professor of law at Harvard, a position which he held for the rest of his life, while he still continued to serve as judge of the Supreme Court. He was strongly opposed to slavery, and for this reason he was very unpopular where the slavery sentiment prevailed. As a judge of the Supreme Court he made a mark for himself and helped to largely mold American equity jurisprudence. Many editions of his law works have been published, and they are still consulted. His law works include special treatises, commentaries and judgments. A collection of his miscellaneous writings was published in 1852. Among the legal works are 'On the Law of Bailments' (1832); 'On the Constitution of the United States' (1833); 'On Equity Jurisprudence, as Administered in England and America' (1836); 'On the Law of Agency' (1839); 'On the Law of Partnership' (1841); 'On the Law of Bills of Exchange' (1843), and others. In his constitutional opinions he was of the school of Washington and Chief-Justice Marshall, advocating just powers for the Union without encroachment upon the rights of the respective States. His judgments in the Supreme Court may be found in the reports (1811-45) of Wheaton, Cranch, Howard and Peters. Consult 'Life and Letters' (1851) by his son William Wetmore Story (q.v.).

STORY, **Julian**, American artist: son of W. W. Story (q.v.): b. Oxford, England. He was educated at Eton and Oxford, studied art at Paris, and in 1889 received the third class medal at the Paris Salon; in 1891 he took the

gold medal at the Berlin Exhibit and in 1900 was awarded the silver at the Paris Exposition. The same year he was made Chevalier of the Légion d'honneur of France.

STORY, (Mrs.) William Cumming, American women's club leader. She is an active worker in patriotic societies as well as women's clubs, and was elected president-general of the Daughters of the American Revolution, 1913. She has served as president of the New York City Federation of Women's Clubs, vice-president New York State Federation of Women's Clubs, etc. Her maiden name was Daisy Allen.

STORY, William Edward, American mathematician: b. Boston, Mass., 29 April 1850. He was graduated (1871) at Harvard, and studied (1871-75) medicine at the universities of Berlin and Leipzig, receiving the diploma of Ph.D. From 1875-76 he was tutor of mathematics at Harvard, becoming successively associate, assistant professor and associate professor of mathematics at Johns Hopkins (1876-89). Since 1889 he has been professor of mathematics at Clark University. He has been editor-in-charge *American Journal of Mathematics* (1878-82) and editor *Mathematical Review*. Many valuable articles on mathematical questions have been contributed by him to the leading 'American, English and German scientific periodicals.

STORY, William Wetmore, American sculptor and author: b. Salem, Mass., 19 Feb. 1819; d. Vallombrosa, near Florence, Italy, 7 Oct. 1895. He was graduated from Harvard in 1838, from its law department in 1840, was admitted to the bar at Boston, and published treatises 'On the Law of Contracts' (1844); and 'On the Law of Sales of Personal Property' (1847), besides three volumes of 'Reports of Cases Argued and Determined in the Circuit Court of the United States for the 1st Circuit' (1847). Two volumes of 'Poems' appeared in 1847 and 1856. In 1848 Story went to Rome, where he afterward chiefly resided as a sculptor and writer. He was United States commissioner on fine arts to the Paris World's Fair of 1879. Among the better examples of his art are statue of Cleopatra (1864); busts of Lowell, Josiah Quincy and Theodore Parker; a statue of Everett in the Boston Public Gardens; a statue of George Peabody for London (1869), placed in replica in Baltimore in 1888; 'Saul'; 'Jerusalem'; 'Semiramis' (1874). Two of his sons, Julian and T. Waldo, were noted in art, the first being a painter and the second a sculptor. Of his further books may be mentioned 'Roba di Roma' (1862); 'Grafitti d'Italia' (1869); 'The Tragedy of Nero' (1875), and 'Fiammetta' (1885). Consult James, Henry, 'William Wetmore Story and His Friends' (Boston 1903); Phillips, M. E., 'Reminiscences of William Wetmore Story' (New York 1898); Taft, Lorado, 'History of American Sculpture' (New York 1903).

STORY, or STOREY, in architecture, a floor of a house or other building, or a set of rooms on the same level or floor. A story is considered the distance from floor to floor, usually 9, 12 or 16 feet apart.

STORY OF A BAD BOY, The, by Thomas Bailey Aldrich, takes high rank among the books in which American authors have recounted in the guise of fiction some of their boyhood experiences—a list that includes among others Mark Twain's 'Tom Sawyer,' William Dean Howells's 'A Boy's Town,' and Charles Dudley Warner's 'Being a Boy.' In 'The Story of a Bad Boy' the author has thinly disguised his name as Tom Bailey, and that of his native town, Portsmouth, as Rivermouth. The seaside setting gives the narrative a flavor as distinctive as that afforded by Tom Sawyer's Mississippi environment. None of the escapades of the bad boy and his friends are in themselves remarkable, but they are told with a thorough understanding of boy psychology, and a pervasive but restrained humor, so that they hold the interest of readers of all ages. Only those of mature years may be able fully to appreciate the satire of a chapter like 'I become a blighted being,' in which Tom tries hard to make his love-sickness overcome the healthy appetite and interests of a boy, but those of Tom's own age can see the humor of the situation, and may even find their understanding aided by secret recollections of their own experiences. The one tragic occurrence, the helpless drifting out to sea of little Binny Wallace, is told with remarkable power. Aldrich was always an artist in prose as well as in verse, and his perfection of form and the charm of his style are seen to advantage in this book. It seems likely to last longer than any of his other prose works with the possible exception of one or two short stories.

WILLIAM B. CAIRNS.

STORY OF GÖSTA BERLING, The, a novel by Selma Lagerlöf, appeared about Christmas-time 1891. In the summer of 1890 a Swedish magazine, the *Idun*, had offered a prize for the best novel of a certain length. Selma Lagerlöf entered the contest with a few chapters from 'Gösta Berling,' a story which was then beginning to take shape in her mind, and won the prize. In 'Gösta Berling' Selma Lagerlöf is a romanticist and represents a reaction against the realism which prevailed at the time. As a child she had absorbed the folk tales of her surroundings, and later on in life it occurred to her like a lightning flash that it was her particular mission to give these stories expression. 'The Story of Gösta Berling' has been called the "prose epic of Swedish country life." The scene is laid on the shores of Lake Fryken (Lake Löven in the story) in Värmland. The hero, Gösta Berling, is a deposed minister, who has been saved by the Mistress of Ekeby from freezing to death and thereupon becomes one of her pensioners in the manor at Ekeby. As the pensioners finally get power in their own hands, they manage the property as they themselves see fit, and their lives are filled with many wild adventures. Gösta Berling is the leading spirit, the poet, the charming personality among a band of revelers. But before the story ends, Gösta Berling is redeemed, and even the old Mistress of Ekeby is permitted to come to her old home to die. In this as in her other works, the authoress shows a marvelous simplicity of style. Everything she touches quickens with new life and takes on a deeper meaning. Consult Ruben Berg, 'Svenska

skalder från nittioalet'; Johan Mortensen, 'Selma Lagerlöf.'

JOSEPH ALEXIS.

STOTHARD, stōth'ard, Thomas, English painter: b. 17 Aug. 1755; d. 27 April 1834. He very early exhibited a taste for drawing. At eight he was placed at school at Stretton, near Tadcaster, where he remained till his 13th year, when he was removed to a boarding-school at Ilford, Essex. On his father's death, about a year after, he was bound apprentice to a drawer of patterns for brocaded silks in London. His apprenticeship was cut short in consequence of the decline of the trade. In 1777 he became a student at the Royal Academy, and in the following year exhibited as his first picture there 'The Holy Family.' In 1791 he was elected an associate of the Academy and in 1794 he became an academician. Among his works may be mentioned his designs for novels by Richardson, Fielding, and Smollett; for Sterne's 'Tristram Shandy'; for Milton's works; for Rogers' Poems and 'Italy'; some historical pictures and his Canterbury Pilgrims. He painted internal decorations of buildings and designed silver plate, medals, etc. He is said to have made 5,000 designs, 3,000 of which were engraved. Consult 'Life' by Mrs. Bray (London 1851) and a second by A. C. Coxhead (London 1906).

STOTT, Henry Gordon, American electrical engineer: b. Orkney Islands, 1866. He studied at the College of Science and Arts, Glasgow, and at the Glasgow and West of Scotland Technical College. He served (1884) with the Glasgow Electric Light Company and (1885-89) with the Anglo-American Telegraph and Cable Company, experimenting at the same time. He was (1889-90) assistant engineer for Brush Electric Engineering Company's plant at Bournemouth, England, then on electric works (1890-91) at Madrid, Spain. From 1891-1901 he was engineer of the Buffalo General Electric Company. Since 1901 he has been superintendent of motive power Interborough Rapid Transit Company and New York Railways Company.

STOUGHTON, stō'tōn, Israel, American colonist: b. England at the close of the 16th century; d. Lincoln, England, 1645. He emigrated to America in 1630 with the company which founded Dorchester, Mass., of which John Endicott was a conspicuous figure, and served the colony as assistant to the governor during a number of years. He was identified with the famous antinomian controversy introduced by Ann Hutchinson and Wheelwright, and having written a pamphlet upon the subject which was displeasing to his fellow townsmen he was removed. He was later restored to his place in the government of the community. In 1639 he was appointed to act with Endicott in a boundary dispute with the Plymouth colony, but in 1644 he left Massachusetts and returned to England where he later on entered the Parliamentary army as lieutenant-colonel. By will he left 300 acres in Dorchester to Harvard University. Consult Quincey, Josiah, 'The History of Harvard University' (Boston 1860).

STOUGHTON, William, American colonist, son of Israel Stoughton: b. about 1630; d. Dorchester, Mass., 7 July 1701. He studied

at Harvard and was afterward graduated at Oxford, where he was fellow from 1652 to 1660 when he was dismissed as a result of the Restoration. Returning to America, he was elected assistant in the Dorchester colony from 1671 to 1686. In 1692 he was appointed lieutenant-governor of Massachusetts, and in this capacity presided over the witchcraft trials at Salem, and he treated the accused with great cruelty. He seems, notwithstanding his travels and education, to have been a man of very narrow calibre. Following the example of his father, he became a liberal patron of Harvard University. Consult Sibley, J. L., 'Biographical Sketches of Graduates of Harvard University' (Cambridge 1873).

STOUGHTON, Mass., town in Norfolk County, on the New York, New Haven and Hartford Railroad, 16 miles south of Boston. Within its limits are the villages of Stoughton, West Stoughton and North Stoughton. The chief manufacturing establishments are woolen mills, rubber works, boot and shoe factories and machine shops. The town has one public high school, 17 district schools, several private schools and a public library, established in 1874. There are several beautiful residential sections and in the southern part of the city are small bodies of water. Pop. over 7,000. Consult Hurd, 'History of Norfolk County' (Philadelphia 1884).

STOUGHTON, Wis., city in Dane County, located on the Catfish River and on the Chicago, Milwaukee and Saint Paul Railroad. It is 15 miles south-southeast of Madison. It has a Carnegie library and manufactures of plows, carriages and wagons, flour mills, etc. Pop. 4,761.

STOUT, George Frederick, English psychologist: b. South Shields, 6 June 1859. He was educated at Saint John's College, Cambridge, of which he became a fellow in 1884. He was Anderson lecturer in comparative psychology at the University of Aberdeen in 1896, and previous to that lecturer on moral science at Cambridge (1894). He became professor of logic and metaphysics in Saint Andrews University in 1903. He was Wilde reader in mental philosophy at the University of Oxford (1898); examiner at London University (1899) and Gifford lecturer at the University of Edinburgh (for 1918-20), and has been editor of *Mind* from 1891. He has published 'Analytic Psychology' (1896); 'Manual of Psychology' (1899) and other similar works.

STOVAINE. This chemical is amylocaine or dimethyl-amino-benzoyl-ethyl-carbinol hydrochloride and its formula is

It crystallizes in small scales that melt at 175° C. It is freely soluble in water, dilute alcohol and acetic ether, slightly soluble in absolute alcohol. Its therapeutic value is as a local anæsthetic (substitute for cocaine). The claims in its favor are that it is a vaso-dilator rather than vaso-constrictor and has but half to one-third the toxic power of cocaine. When administered subcutaneously it is not an anodyne, but produces analgesia in epidural or epidermal in-

jections, especially in cases of neuralgia, including sciatica. It is favored in ocular surgery for its rapid action. Dentists employ stovaine preceding extractions.

STOVES AND HEATING APPARATUS. Any system of heating must necessarily include three things, the combustion of fuel in a fireplace, stove, furnace, steam or hot-water boiler; a system by which the heat is transmitted to its destination with the least possible loss; and a system of diffusion, by which the heat is conveyed to the air in a room, and to its walls, floors, ceilings, etc. The simplest and most economical method of heating to instal is the stove, which requires no system of transmission, but by radiation and convection diffuses the heat directly to the air and to the objects in the room. Though this method has not been entirely superseded in dwellings by the hot-air furnace, owing to the cost of installing the latter, the furnace has largely done away with use of the stove solely as an apparatus for heating purposes, beside which the furnace has many advantages over the stove, as such. The hot-air furnace is generally constructed of brick or iron plates and provided with a brick-lined firepot; there is a combustion chamber over the fire, and between these latter two and the outside casing is left a space for the circulation of air. Through a box or pipe, called the "cold-air box," located at the bottom of the casing, fresh air is brought from outside, enters the space between the casing and the firebox, passes over the heated surface of the firepot and combustion chamber, and, by means of pipes at the top of the casing which connect with the registers, is transmitted to the various rooms of the house.

The furnace in its turn was followed by the steam boiler which transmits the steam to radiators throughout the house, and from them the heat is diffused to the air in the room. This method of heating has come into use largely as the office building has been increased in size, and the majority of such buildings are now heated by steam. Gas and oil stoves have also become valuable as means of heating isolated rooms in a building or house, not otherwise connected with any heating appliances.

Stoves.—In 1490 the first stove was reported as being made in Alsace, and in 1509 others were cast in Islenberg. The first blast furnace erected in this country at Lynn, Mass., in 1642, turned out a small round-bottomed kettle with a cover, probably the first stove of any description made in this country. The industry lagged for nearly a century, and it was not till the middle of the 18th century that the manufacture was pushed to any great extent. About 1735 Christopher Sower, of Germantown, Pa., began to manufacture the jamb-stove, which was the first attempt to heat other rooms than the one in which the great brick fireplace was located. This jamb-stove consisted of a cast-iron box built into the side of the kitchen fireplace, one end opening in the adjoining room, the other being heated by the fire, so that when the door of the jamb-stove was opened, a small amount of heat was transmitted to the room.

In 1744 the manufacture of Franklin stoves was commenced in Philadelphia. This stove, the invention of Benjamin Franklin, consisted of a cast-iron open fireplace, jutting out from

the chimney, and thus the heat was thrown out from three sides into the room, instead of only the one side, as in the jamb-stove. Between 1752 and 1760 the six-plate, or box-stove, which was the pioneer of the many modern forms of heating apparatus, was made in Marlboro, Va. Stoves were made in 1760 by Baron Steigel of Letitz, Pa., and in 1786 box-stoves were made in Philadelphia, but were not put together there, that work being done at Providence, R. I., and Troy, N. Y., whither the plates were shipped. In 1802 Isaac Orr began the manufacture of the cylindrical or oval stoves of sheet iron at Philadelphia and in New Hampshire. This was the forerunner of the oval regulator stove, having a fire-damper, automatically opened and closed by the difference in expansions of a brass rod and the sheet-iron stove-body. In 1820 the Conant stove was made at Brandon, Vt., and the Woolson stove soon followed, being first made at Brandon, but they were later manufactured in Massachusetts, Cleveland and Detroit. In 1836 a stove having an illuminated case of cast iron and mica, enclosed flues, a check-flue and a direct draft damper, was made by James Atwater of New York, and almost simultaneously the Stanley square heating-stove was brought out. The cylinder-stove, invented by Dr. Bushnell in 1845, except for the fact that it was cylindrical and the inside was lined with fire-clay, was similar to the Stanley stove, the latter having return and exit flues enclosed in the four corners, whereas the former had a pipe at the back through which the heat made its exit after having come down the four pipes or flues in the corner to the hollow base. The next in succession was the round or oval gas burner or surface burner, made of sheet iron, and having the flues which returned the heat to the base enclosed in the body of the stove. It should be understood that these "gas-burning" stoves consumed coal, the reason for the name "gas-burning" being that they were assumed to consume all the gas emitted by the coal. In these gas-burners also the coal was more thoroughly burned out by having perforated firepots and perforated gas rings at the top of the brick. Fuller, Warner and Company of Troy, N. Y., made the style of oval and round parlor stoves most generally used, the P. P. Stewart.

The base-burner has been in use for many years, one of the first to be constructed being the self-feeder, patented by Jordan L. Mott, Sr., of New York, in 1833; the plan of his stove being to feed the coal from a magazine to the firebox, and to use the chestnut size of anthracite coal. This was followed in 1852 by the self-feeding base-burning stove, and in 1862 by the "Morning Glory," both of which were the inventions of D. G. Littlefield of Albany, N. Y.; then came the "American" of Van Wormer & McGarvey of Albany, N. Y., and in 1863 the revertible-flue gas-burner with the magazine attachment, the production of Hales and Treadwell, in Albany. Since then there have been innumerable styles of stoves introduced, with many more or less valuable changes and additions. The following are the most important of these: the base-burner having a small mica window opposite the grate, by Hunt and Miller of Hudson (1865); the anti-

clinker direct draft base-burner, by James Spear of Philadelphia (1871); "Keep's Side-Burner," having a full mica section below and above the firepot, by W. J. Keep (1871); the "Argand" base-burner, a combination of the "American" with an anti-clinker grate and the full double illumination, by Perry and Company of Albany (1873); the "Splendid" by Fuller, Warner and Company (1875); the "Garland" by the Michigan Stove Company (1876); Keep's square-base and square-sided, round front and round firepot, called the "Art Garland," by the Michigan Stove Company (1884); the "Hub" base-burner, by Smith and Anthony of Boston (1884); the Keep "Reflector Art Garland," by the Michigan Stove Company (1887); and many other makes, including the oval sheet iron stove, known as the "Tamale," and the P. D. Beckwith "Oak" stove, having fluted firepot, steel drum and airtight fittings.

In the cooking stove there has been as much change as in the stove used for purely heating purposes. The pioneer in this line was the James stove, a nine-plate, with the oven on the side of the stove. The next in succession was the Conant stove, invented in 1819, which had the oven directly over the firepot and doors at both ends, but as the fire underneath the oven heated the bottom too quickly, this style was soon abandoned. The Woolson stove of Claremont, N. H., having the oven at the side, the heat being thrown under or over it by means of dampers, was next on the market, but as the fire caused the oven to bake more rapidly on the near side, the oven was next placed at the rear and above the boiler-holes. In 1833, Stanley invented the rotary cook stove, with the cooking holes and firebox on the same level as the oven. The next step along progressive lines came in 1810-20, in shape of an oval stove, the invention of a Mr. Hoxie of Salisbury, Conn., in which the fire, having gone down the two end flues and met at the bottom, passed to the chimney through an aperture in the hearth of the fireplace over which the stove was situated. P. P. Stewart patented two stoves, one in 1828, the other in 1850, in the first of which the firebox was hung in the upper part of the oven, thus throwing off heat from three sides while the flame passed all around the oven on the outside and on the pipe collar on top of the stove. The latter, the large oven stove, had a sheet flue underneath with three flues at the rear. At about the same time, 1850, the curved plate which dumped the ashes from the grate into the pit in the hearth was invented by Samuel Pierce, and since then only minor changes have been made in construction, the water-tanks, reservoirs, grates, etc., being rearranged, various methods of open ventilation, return-flue construction and different styles of ornamentation being introduced.

The improved kitchen cooking stove when of large size was named "range." A sheet-iron range, in which the grate containing the fire was suspended inside a sheet-iron casing, the heat thus coming from the fire direct, was placed on the market in Boston, in 1850, by a Frenchman named Gillette. About the same time a similar range was made in New York by Duparquet, Huot and Moneuse, but they

later made a radical change in the construction by placing flues around the oven, as at present, and the oven was made a separate part of the construction. These two were followed, in 1885, by the wrought-iron range of John Van of Cincinnati, but with the many rapid advances made in the manufacture of steel, the use of wrought iron has largely given place to the use of blue polished steel and aluminum painted steel.

The manufacture of stoves is largely carried on in the West—Ohio, Illinois and Michigan being the largest producers. The earliest factories in the East where stoves were made exclusively were at Troy, Albany and New York. The West then began to loom, the first foundry being established in Detroit about 1830, known as the Hydraulic Iron Works, which was followed by Dwyer and Brother in 1861. This firm later became the Detroit Stove Works, which, in 1871, was followed by the Michigan Stove Company, and in 1881 by the Peninsula Stove Company and others. The competition thus engendered between western and eastern manufacturers soon led to the establishment of branch foundries by the eastern people in western cities, and Chicago became the centre of distribution. Later Ohio took the lead, and in 1915 one-fifth of the production of stoves and furnaces was in that State. The statistics of the trade are meagre, but for the year 1900 the output of stoves was valued at \$35,446,600, distributed through the States as follows: Pennsylvania, \$5,209,000; Michigan, \$4,935,000; New York, \$4,913,700; Ohio, \$4,384,200; Illinois, \$3,801,000; Massachusetts, \$2,061,800; Missouri, \$1,921,000; Indiana, \$1,439,500; Tennessee, \$1,280,000; Kentucky, \$1,044,000; Wisconsin, \$972,000; etc.

Thereafter the census placed together the manufacturers of stoves, furnaces, and gas and oil stoves, and the total annual value of the products is over \$75,000,000.

Oil and Gas Stoves.—Oil stoves for domestic use became common about 1875. The earlier types were simply large lamps, burning kerosene, and having a fixture on top for supporting a pan, kettle or cooking or heating utensil. Very broad wicks were employed, and a circular burner and wick were also introduced, that gave good results. These oil lamps or oil stoves had to be kept very clean to secure good combustion, as they delivered a great deal of carbon, which tended to clog the mechanism. It was a decided improvement when the vapor-burning stove was later introduced. In this the naphtha or other light product of petroleum was stored in a small metal tank, and led through a pipe to one or more burners—usually a set of burners, arranged like the top of a stove. The aperture to the burner was very small, and the slight stream of naphtha that flowed was easily vaporized, so that after a burner had been lit a minute or less, it ceased to burn oil directly as the pipe near the burner became hot enough to vaporize the oil, and delivered vapor to the burner. This vapor could be mixed with air, on the principle of a Bunsen burner, and thus the consumption of fuel was both economical and safe, for the tank was at a distance from the flame. Oil stoves of a variety of types, utilizing the principles here described, are on the market, and

are not only an economical method of heating, but very convenient as to portability. They have the disadvantage, however, of rapidly consuming the oxygen in a small room, and constant ventilation is required to render the air fit to breathe.

Gas stoves have been made and used for a long time, but were never popular until after the general agitation for lower-priced gas had resulted in bringing ordinary illuminating gas resulted in bringing illuminating gas to a price below \$1.50 per 1,000 cubic feet. An exception region of the Middle West where they first came into common use in the 60's and 70's. About 1890 the gas companies of the United States began a concerted effort to introduce gas stoves to increase the sale of their commodity. The common type of heating stove offered was of the radiator type, with a row of burners in the base, and large metal tubes directing the heat toward the top, so as to afford plenty of radiating surface. These were made of sheet iron, usually ornamented with nickel, in various sizes, and they have become common for household use, where rooms are not heated by furnace or steam. For cooking purposes, the gas companies have supplied gas ranges, patterned after the coal ranges on top, and as to oven conveniences, Rosette burners are placed where the "holes" are in a coal range, and mixers employed to admit air to the burners, so as to secure hot blue flames, with a minimum consumption of gas. These gas ranges have become very popular with housewives, for they save the dirt and dust of coal and ashes, involve cost only when in actual use and are easily lit and turned out. They are often used in summer time alongside coal ranges, which are allowed to lie idle, the reason being that the gas range creates less heat in the room, and is, therefore, more comfortable. Despite the fact that gas fuel generally costs considerably more than coal, the conveniences of the gas stove and gas range have resulted in a steadily increasing use.

Furnaces.—The first hot-air furnace for supplying pure heated air to rooms was probably that constructed by Franklin in 1744. This was a sheet-iron oblong box, burning wood, the smoke passing into the chimney over the top of the flat chamber behind the fire, and between it and the rear back of the stove. The cool air entered this flat hollow chamber through a pipe, and when heated passed through small holes in the side of the chamber into the room. This style of apparatus was not much improved upon till the beginning of the 19th century when in 1808 Daniel Pettibone of Philadelphia took out a patent on a stove for rarifying air by heat. This was followed by the warm-air furnace of William A. Wheeler of Worcester, Mass. (1835); by that of Gurdon Fox of Hartford, Conn. (1835-40); the Blaney and the Culver; the Boynton, made by Richardson and Boynton; the Thatcher and others. The reduction of the price of furnaces has made their use more common, till now nearly every large dwelling-house has one. Furnaces may be divided into two general types, the direct and indirect draft. The better class of direct draft furnaces have a radiator, generally placed in the top, through which the gases pass before reaching the smoke-

pipe, and usually have but one damper combined with the cold-air check. In the cheaper styles of direct-draft furnaces, this radiator is done away with, the gas passing directly into the smoke-pipe, but this system wastes much heat that is utilized by the better grade of furnace. In the indirect draft type of furnaces the radiator is located near the base and the gases pass down through flues to it, thence upward and through another flue to the pipe. This style of furnace has a direct-draft damper in addition to the damper in the pipe, thus allowing the gas to escape to the chimney more easily.

The matter of grates and firepots is most important. The most approved form of grate is the revolving triangular pattern, consisting of toothed triangular bars, connected by gears and turned by means of a detached lever. Firepots are usually made of cast iron or of steel plate lined with fire-brick, the pot ranging in depth from 12 to 18 inches. In a wrought-iron or steel furnace this fire-brick lining is necessary because the intense heat may harm the outside shell, but it has not the advantage of giving off heat when the coal is first put on, as does the furnace having the cast-iron firepot.

The combustion chamber, or space above the firepot, should be of sufficient size to allow the gases to become thoroughly mixed with the air passing up through the fire or through the openings of the feed door. The radiator, generally constructed of cast iron or steel plate, is used as sort of a reservoir for the gases and air passing over the furnace, till the air has extracted a considerable portion of the heat from the gas. The cold-air box should be large enough to supply a volume of air sufficient to fill all the hot-air pipes at the same time, the general size or area of the cold-air box being three-fourths the combined area of the hot-air pipes.

Steam and Hot Water.—Heating by means of hot water has been in use since time immemorial, and was known prior to the Christian Era, for Seneca mentions the methods by which water was heated in the *Thermae* at Rome, that of passing water through a coil of brass pipes which passed through a fire. This method was used in France in 1777 by M. Bonnemain, and in London, in 1817, by Marquis de Chataignes, for heating a conservatory, and in 1822 an Englishman named Bacon introduced the method of using an inclined pipe of large dimensions, but this was not successful because of imperfect circulation. The first hot-water apparatus introduced in this country was the Perkins system, introduced from England by Joseph Nason in 1842. Hot-water heating in the United States has been an evolution since 1880, the most popular heaters at the beginning of this period being the Gurney and the H. B. Smith. In 1885 the Bolton heater was introduced by the Detroit Heating and Lighting Company, the Mouat heater was the next in succession, and since that time the improvements have been so many and the demand so great that the price of the hot-water plant has been reduced till it is within the reach of the average householder. Hot-water heating is preferred by some to steam because the heat is available as soon as the temperature of the water is higher than that of the room, whereas

steam yields no heat until 212° degrés is passed and steam generates, filling the pipes. But in large installations steam is cheaper and has other advantages.

The practice of heating buildings by steam was begun about 1845, the first building to be so heated being the Eastern Hotel of Boston, and the first factory building the Burlington, Vt. Woolen Mill. The system by which these buildings were heated was introduced by Joseph Nason, and consisted of small wrought-iron pipes. From this small beginning have developed the many intricate systems of apparatus now used for warming buildings.

There are two systems of heating by steam, the direct and the indirect, the former being used in all classes of buildings, both by itself and in combination with other systems. The direct system consists of a furnace and boiler for the combustion of fuel and the generation of steam; a system of pipes, by means of which the steam is conveyed from the boiler to the radiators and the condensed water returned to the boiler, and the radiators or coils of pipes placed throughout the rooms of a building for the purpose of diffusing the heat to the air. The types of boilers used are many and various; the cast-iron sectional boiler is more commonly used for dwelling-houses and the tubular or water-tube boiler for larger buildings. In the boiler used for heating purposes only it is not necessary to carry a pressure of more than two to 10 pounds, the condensation flowing back to the boiler by gravity. When under a high pressure, the steam for the heating system is forced through a reducing valve and the condensation returned to the boiler by means of a pump or return trap. The system of diffusing the heat by radiators is not standard, no particular one being of greater benefit than another. There are the common cast-iron sectional radiator; the vertical wrought-iron pipes screwed into a cast-iron base; the cast-iron wall radiator, which does not obstruct the flow, and the coils of iron pipes placed along the ceiling or walls, these latter being of late years ornamented and frequently gilded.

Indirect steam heating has the advantages both of the furnace and of the direct steam, but the cost of installing the system is greater. The main difference between the two lies in the radiator, in the indirect system a special form of heater being placed beneath the floor and encased in galvanized iron or brick work. Connected with the space beneath the heater is a cold-air box and warm-air pipes at the top are connected with registers in the floors or walls as previously described for furnaces, so that the air in passing through the spaces between the sections of the heater becomes warmed and rises to the rooms above. As compared with furnace heating this method has one great advantage, being less affected by outside wind pressure, as long runs of horizontal pipe are avoided and the heaters can be placed near registers. See FURNACE; HEATING AND VENTILATION; ELECTRIC FURNACES; etc.

STOWE, Calvin Ellis, American educator: b. Natick, Mass., 6 April 1802; d. Hartford, Conn., 22 Aug. 1886. He was graduated at Bowdoin College in 1824, and at Andover

Theological Seminary in 1828. In 1829 he became an editor of the *Boston Recorder*, but abandoned journalism for the chair of Greek at Dartmouth in 1830. In 1832 he was called to Lane Theological Seminary, Cincinnati, and in the same year was married to Harriet Elizabeth Beecher, author of 'Uncle Tom's Cabin.' He was professor of divinity at Bowdoin in 1850, and in 1852 became professor of sacred literature at Andover, retiring in 1864. His writings include 'The Hebrew Commonwealth' (1829); 'Lectures on the Sacred Poetry of the Hebrews' (1829); 'Introduction to the Criticism and Interpretation of the Bible' (1835); 'Elementary Education in Europe' (1837); 'The Religious Element in Education' (1844); 'Origin and History of the Books of the Bible' (1867).

STOWE, Emily Howard (née Jennings), Canadian suffragist and physician: b. South Norwich, Ontario, 1831; d. 1903. She was educated at Provincial Normal School, Toronto, then taught at school. She married John Stowe, of Norwichville, Ontario. In 1867 she was graduated at the New York Medical College for Women and fought all opposition in Canada till admitted (1880) a member of the Ontario College of Physicians and Surgeons, being the first woman physician permitted officially to practice in Canada. The Toronto Woman's Literary and Science Club was organized (1877) by her to become later a suffragist club and (by 1883) widows and spinsters were granted the suffrage at municipal elections in Ontario. In 1893 she organized the Dominion Woman Suffrage Association and was elected its president.

STOWE, Harriet Elizabeth Beecher, American writer: b. Litchfield, Conn., 14 June 1811; d. Hartford, Conn., 1 July 1896. She was a daughter of Rev. Lyman Beecher (q.v.) and sister of Henry Ward Beecher (q.v.). She was educated at Litchfield and then at Hartford, under her sister Catherine, whom she joined in teaching in her school there. In 1832 the sisters removed to Cincinnati, where their father was appointed president of Lane Theological Seminary. In 1836 she was married to the Rev. Calvin E. Stowe, a teacher in the seminary, who in 1850 removed to Brunswick, Me., on being appointed a professor in Bowdoin College, soon after exchanging this post for a similar one at Andover. Mrs. Stowe published in 1843 *The Mayflower*. She had become familiar with the evils of slavery during her residence at Cincinnati, and the work by which her name became known throughout the world—'Uncle Tom's Cabin,' a direct attack upon slavery, was (in 1851-52) contributed in serial form to *The National Era*, an anti-slavery newspaper published at Washington. The story was to some extent based on the experiences of Josiah Henson (q.v.). It was defective in style and construction, but was vividly done. It did not perfectly render Southern life, and the injustice of some of its presentations has been much discussed. It certainly helped to liberate the slave, though its effect was enhanced by political conditions. As a serial it was successful; but it was not until it was published in book form in 1852 that it became famous. In five years over half a million copies of the book were sold in the United States; and its sale in England was

very large. It became almost immediately famous, was translated into many foreign languages and published in innumerable editions. In 1853 Mrs. Stowe visited Europe, and this furnished her material for her 'Sunny Memories' published the following year. In 1868 she was associated with Donald G. Mitchell on the editorial staff of *Hearth and Home*. In 1879, when the 'Illustrated' edition was published, there were in the British Museum 43 English editions and 19 translations. None of her subsequent works attained anything like the same popularity. Among her works are 'Sunny Memories of Foreign Lands' (1854); 'The Mayflower, and Miscellaneous Writings' (1855); 'Dred: A Tale of the Great Dismal Swamp' (1856); 'The Minister's Wooing,' her most artistic work (1859); 'The Pearl of Orr's Island' (1862); 'Agnes of Sorrento' (1862); 'Reply to the Address of Thousands of Women of Great Britain and Ireland to their Sisters of the United States' (1863); 'House and Home Papers' (1864); 'Stories about our Boys' (1865); 'Little Foxes' (1866); 'Religious Poems' (1867); 'Queer Little People' (1867); 'Daisy's First Winter and Other Stories' (1867); 'The Chimney Corner' (1868); 'Men of Our Times' (1868); 'Old-town Folks' (1869), a popular study of New England life; 'The American Woman's Home' (1869), with Catherine E. Beecher; 'Lady Byron Vindicated' (1870); 'Little Pussy Willow' (1870); 'Pink and White Tyranny' (1871); 'Sam Lawson's Fireside Stories' (1871); 'My Wife and I' (1871); 'Lives and Deeds of Our Self-Made Men' (1872); 'Palmetto Leaves' (1873); 'Woman in Sacred History' (1873); 'Betty's Bright Idea, and Other Tales' (1875); 'We and Our Neighbors' (1875); 'Deacon Pitkin's Farm, and Christ's Christmas Presents' (1875); 'Footsteps of the Master' (1876); 'Captain Kidd's Money, and Other Stories' (1876); 'The Ghost in the Mill, and Other Stories' (1876); 'Poganuc People' (1878); 'A Dog's Mission' (1881). Consult Field, 'Life and Letters of Harriet Beecher Stowe' (1897); Stowe, C. E., and L. B., 'Harriet Beecher Stowe' (Boston 1911); 'Life,' by her son, C. L. Stowe (ib. 1889). See **UNCLE TOM'S CABIN**.

STOWELL, Ellery Cory, American professor of international law: b. Lynn, Mass., 12 Dec 1875. He was graduated (1898) at Harvard, traveled (1901-02) in the Orient and Europe, attended the University of Berlin (1903-04) and University of Paris (1904-07). He was appointed secretary of the College of Political Sciences, Washington (1908-09); instructor of international law at George Washington University (1908-10); assistant professor of international law at the University of Pennsylvania (1910-13). He filled the last-mentioned position at Columbia from 1916. From 1910-12 he was assistant editor *Annals of American Academy of Political and Social Science*. In 1907 he was a member attending the Second Peace Conference at The Hague and (1908-09) was secretary of the American delegation of the Naval Conference at London. He has written 'Le Consul' (1909); 'Consular Cases and Opinions' (1909); 'The Diplomacy of the War of 1914' (published in part).

STRABISMUS. See **VISION, DEFECTS OF**.

STRABO, strá'bō, Greek geographer and historian: b. Amasia, about 64 B.C.; d. 19 A.D. He received a good education and adopted the stoical philosophy. He studied for some time in Rome and was with Aelius Gallus in Egypt and Arabia in 24 B.C. He returned to Rome 20 B.C.; and from this time on made that city his home; though he traveled much, for, as he states himself, he had been from Armenia in the East to Sardinia in the West; and from the Pontus Euxinus on the North, to the borders of Ethiopia. It seems probable that these journeys were made in pursuit of knowledge and information for his literary labors. He wrote a historical work in 43 books, which is lost. It formed a continuation of the history of Polybius to the battle of Actium. The extant fragments of it are collected in Müller's 'Fragmenta Historicorum Græcorum.' His great work on geography, in 17 books, has been preserved entire, with the exception of the seventh book, of which there is only an epitome. It includes notices of important political events and of chief cities and their great men. Eight books are given to Europe, six to Asia, one to Egypt and Libya. Internal evidence shows that he did not complete the plan he had laid out for this work. The best critical edition is that by Kramer (Berlin 1844). Consult Dubois, 'Examen de la Géographie de Strabon' (1892); Hamilton, 'A Translation of Strabo's Geography.'

STRACHAN, John, Canadian bishop: b. Aberdeen, Scotland, 12 April 1778; d. Toronto, Canada, 1 Nov. 1867. He was educated at grammar school, then (1793) at King's College, Aberdeen. While continuing his studies at the college he taught at schools, till he was graduated in 1797. In 1799 he went to Canada to take charge of a new college projected by Governor Simcoe at York (near Toronto). The project failing, he took to teaching at a private school at Kingston which he established. He abjured his adherence to the free church and joined the Church of England and was ordained minister in 1803, becoming curate at Cornwall. In 1807 he was made LL.D. of Saint Andrew's and (1811) D.D. of Aberdeen. He was made (1812) rector of York (Toronto) and chaplain to the troops as well as master of the grammar school and promoted (1825) to archdeacon. In 1839 he was made first bishop of Toronto. He made great success during his visitations which were an annual episode. He had more than doubled the number of churches in five years, also establishing common schools throughout the province and a statute was passed establishing 20 grammar schools affording classical education. He obtained 500,000 acres (1827) to endow a university at Toronto, and, after difficulties, succeeded in its foundation. In 1850 it was taken from the Anglican Church and made non-sectarian. Strachan made vehement appeals to the laity and, assisted by a royal charter, formed another university under the name Trinity College. He was Canada's greatest advocate of the Church of England, for which sect he gave business energy, diplomatic talent and a devoted zeal. Consult Bethune, 'Mémorial of Bishop Strachan' (To-

ronto 1870); Mockridge, C. H., 'The Bishops of the Church of England in Canada and Newfoundland' (Toronto 1896).

STRACHEY, strā'chī, John Saint Loe, English journalist: b. 1860. He was educated at Oxford and has been a London journalist from 1884. He was editor of the *Cornhill Magazine* (1896-97) and is now editor and owner of *The Spectator* and proprietor of *The Country Gentleman*. He has published 'From Grave to Gay'; 'The Manufacture of Paupers' (1907); 'Problems and Perils of Socialism'; 'The Practical Wisdom of the Bible' (1908); 'A New Way of Life' (1909).

STRACHEY, William, English colonist and historian: b. England, about 1585. Nothing definite is known of him before the sailing of a party of colonists, 15 May 1609, bound for Virginia. He sailed in the *Sea Venture*, which was wrecked on the Bermudas in July. An account of the wreck was written by Strachey and published in 'Purchas his Pilgrimes' (1625) under the title 'A True Repertory of the Wracke and Redemption of Sir Thomas Gates upon and from the Islands of the Bermudas, his coming to Virginia and the state of that Colony.' Strachey and his party finally reached Jamestown, 23 May 1610, where he was appointed secretary and recorder of the colony by Lord De la Warr. He returned to England in 1611 and he edited the laws promulgated for Virginia by Sir Thomas Gates and Sir Thomas Dale, 'For the Colony in Virginia Britannia Lawes Divine, Morall and Martiall, Alget qui non ardet' (1612). His larger work on Virginia, 'The Historie of Travaile into Virginia Britannia, expressing the Cosmographie and Comodities of the Country, Together with the Manners and Customes of the People. Gathered and Observed As Well by those who went First Thither, As Collected by William Strachey, gent. Three Yeares thither Employed Secretarie of State,' failed of finding a publisher during his lifetime and was brought out by the Hakluyt Society in 1849. This is regarded as the most ably written of the numerous accounts of the settlement of Virginia. Nothing is known of the history of Strachey subsequent to 1618 when he tried unsuccessfully to interest Bacon in the publication of his book. Consult Brown, Alexander, 'Genesis of the United States' (Boston 1891).

STRADELLA, Alessandro, Italian singer and composer: b. Naples, 1645; d. Genoa, 1681. After receiving his early musical training at Naples, he subsequently went to Venice, and thence to many other cities of Italy where he was greeted with enthusiasm. He was constantly threatened with death or injury by the rivals to whom his triumphant success was intolerable. While he fortunately escaped from the hands of his would-be assassins at Rome, he was severely wounded by bravos at Turin, and an attack made upon him at Genoa proved fatal. The most exquisite of his many compositions is the oratorio 'San Giovanni Battista.' Flotow's opera of 'Stradella' is concerned with the career of this composer. Consult Crawford, F. M., 'Stradella' (London 1911); Richard, P., 'Stradella et les Conarini' in the Paris musical journal 'Le Ménestrel' (1865, No. 51; 1886, No. 18).

STRADIVARI, strā-dē-vā'rē, Antonio, Italian violin-maker: b. Cremona, 1644; d. 1737. He was a pupil of Nicolo Amati, in whose employment he remained until about 1679, when he began making on his own account. It was he who settled the typical pattern of the Cremona violin, and his instruments for tone and finish have never yet been excelled. His improvements consisted chiefly in lowering the height of the arch of the belly, in making the four corner-blocks more massive, in giving greater curvature to the middle ribs, in altering the setting of the sound-holes, and in making the scroll more massive and prominent. He made a great number of violins, but a few of which are now in existence. He reached his greatest perfection in his art about 1714. He also made many other kinds of musical instruments, but it is on his violins of all kinds that his fame rests. Consult Hill, W. H., 'Antonio Stradivari' (New York 1909); Riechers, A., 'The Violin and the Art of its Construction' (London 1905).

STRAFFORD, strāf'ōrd, Thomas Wentworth, 1st EARL OF, English statesman: b. London, 13 April 1593; d. by execution Tower Hill, 11 May 1641. Entered at Saint John's College, Cambridge, in 1607 he became a student of the Inner Temple, and in 1611 received the honor of knighthood. He was returned for Yorkshire to the Parliament which met 5 April 1614, and in 1621 he was again chosen. On the convening of the new Parliament he was one of the six popular members who were prevented serving their country in that assembly by being appointed sheriffs for their respective counties. When Charles, among other expedients for raising money, had recourse to a forced general loan, Wentworth refused to pay his contribution, and was first imprisoned in the Marshalsea. In 1628 he took his seat for Yorkshire, and became one of the most conspicuous advocates of the petition of right. In 1628 he was created Baron Wentworth, and some months afterward a viscount and privy-councillor, and on the resignation of Lord Scrope, nominated President of the North. The assassination of Buckingham soon after removed an obstacle to his further promotion, and he became so influential in the king's council that his powers in the four northern counties over which he presided were enormous. The legality of some of the powers of the Council of the North, created by Henry VIII, had been questioned by judges in the reign of Queen Elizabeth, and these powers had been greatly increased at the instance of Wentworth. He was selected by Laud to proceed to Ireland as lord-deputy in 1632. He greatly improved the state of the country, both as regarded law, revenue and trade. By a considerable outlay at his own risk he introduced the growth of flax, established looms, brought workmen from France and Flanders to work them, and thus endowed the country with a new and most valuable industry. But, at the same time, nothing could be more arbitrary than his system of government, it being his boast that he had rendered the king as absolute in Ireland 'as any prince in the whole world could be.' He returned with the full title of lord-lieutenant, with a view to gain subsidies and troops,

in which he fully succeeded. He again repairing to England took the command in the north, but found himself obliged to retire before the Scottish army, and to retreat to York. The very first movement of the party opposed to arbitrary power was to impeach him for high treason, with which charge Pym appeared at the bar of the House of Lords in November 1640. The articles of impeachment, at first nine in number, were afterward increased to 28, the object of which was to convict him of an attempt to subvert the fundamental laws of the country. As in the case of Laud, it was easy to prove that he acted as a friend and promoter of arbitrary measures, but not to substantiate any particular fact to justify a capital charge. There can be no doubt, however, that his design was to subvert the fundamental laws and liberties of his country, and to enable the king to rule absolutely and without control. Although treated with the extreme of legal rigor and debarred the assistance of counsel, his own great abilities and force of mind supplied every deficiency. "And never man," says Whitelocke, the chairman of the impeaching committee, "acted such a part, on such a theatre, with more wisdom, consistency, and eloquence, or with greater reason, judgment, and temper." His defense, indeed, was so strong that the original impeachment was deserted for the unjustifiable proceeding of a bill of attainder. The bill passed the Commons by a great majority, and was carried in the Lords by a feeble one. The king, who had imprudently endeavored to stop the bill by his personal interference, had not sufficient firmness to redeem the pledge of safety which he had previously given, but yielded to the advice of his counsellors, backed by a letter from Strafford himself, who urged him, for his own safety, to ratify the bill. Charles ratified the bill of attainder on 10 May 1641, and two days later Strafford was executed. Browning's 'Strafford: An Historical Tragedy' (1837), is based on his career. Consult Browning, Robert, 'Prose Life of Strafford' (Boston 1892); Firth, C. H., 'Papers Relating to Thomas Wentworth, First Earl of Strafford' (London 1890); Foster, 'Statesmen of the Commonwealth' (1836); Gardiner, S. R., 'History of England' (10 vols., New York 1883-84); Radcliffe, 'The Earl of Strafford's Letters and Dispatches' (London 1739); Traill, H. D., 'Lord Strafford' (London 1889).

STRAIGHT, Willard Dickerman, American consul-general and financier: b. Oswego, N. Y., 31 Jan. 1880. He studied at the Bordentown, N. J., Military Institute (1897) and was graduated (1901) at Cornell. He served (1902-04) in the Chinese Maritime Customs at Nanking and Peking, became American vice-consul-general and private secretary to American Minister at Seoul in 1905. From 1906-08 he was consul-general at Mukden. In 1909 he was appointed representative in China for a group of American bankers. In 1917 he was commissioned to the major-adjutant general's department United States Reserve.

STRAIGHT TICKET. See **BALLOT**.

STRAIGHT COLLEGE, an educational institution in New Orleans, La., open to pupils of both sexes without regard to race or

nationality. It was the pioneer school in Louisiana to provide education privileges for the negro race. It was founded in 1869 by the American Missionary Association (Congregational), and its first building was erected by the United States government. At first it offered only courses of elementary and secondary grades, but as the work steadily prospered higher departments were added. The organization now includes (1) the Daniel Hand Primary School; (2) the Grammar Department; (3) the College Preparatory Department; (4) the Industrial Department; (5) the Normal Department; (6) the College Department; (7) the Department of Music; (8) the Theological Department. There is also a night school. The College Department offers two courses, classical and Latin scientific, and confers the degrees of A.B. and B.S. The preparatory department provides two corresponding secondary courses. The normal course requires four years' study beyond the grammar grades, but the first year's course is identical with the first year of the College Preparatory Department. The Theological Department provides courses for those who are graduates in a classical course and for those who have had only English courses. There is, in addition, a course in Bible Study. Industrial training is given only in connection with the regular school work. The courses in the Industrial Department are Domestic science, sewing and dress-making, wood-working, mechanical drawing and printing. The college has a central location; the buildings include the main edifice, replacing the former building destroyed by fire in 1891, Stone Hall, a dormitory for girls, and Whittin Hall, a dormitory for boys. The college depends partially for its support on the American Missionary Association. The tuition fees are small, and the older students are allowed to pay a part of their expenses by doing work. The average annual attendance of students is over 600. The teaching staff numbers 25.

STRAIN, Isaac G., American naval officer: b. Roxbury, Pa., 4 March 1821; d. Aspinwall, Colombia, 14 May 1857. He was appointed midshipman in the United States navy in 1837; in 1845 led an exploring expedition into the interior of Brazil and in 1849 made the overland journey from Valparaiso to Rio Janeiro. He received rank as lieutenant in 1850, was engaged in that year with the commission which laid out the boundary line between United States and Mexico, and in 1854 was in charge of the expedition for the survey of the Isthmus of Darien. The extreme hardships which his command was called upon to endure in this latter expedition and the skill and courage with which Strain met the difficulties that beset him brought him favorably before the public. He was assigned to the *Arctic* in 1856 and was engaged in making soundings in the North Atlantic Ocean for the purpose of ascertaining the possibilities of laying a submarine cable between United States and Great Britain. He wrote 'The Cordillera and Pampa' (1853); 'The History and Prospects of Interoceanic Communication' (1856). Consult Headley, Joel Tyler, 'Darien Exploring Expedition, Under Command of Lieutenant Isaac G. Strain, U. S. N.' (1885).

STRAIT OF MAGELLAN. See **MAGELLAN, STRAIT OF.**

STRAITS SETTLEMENTS, East India, a British colony consisting of Singapore, Penang, Malacca and several isolated possessions on and adjacent to the Malay Peninsula, and bounded by the Federated Malay States. Singapore includes the island of that name, the Cocos (Keeling) Islands, and Christmas Island. The total area of the colony is 1,600 square miles, and the combined population about 762,000, the greater portion being divided between Chinese and Malays, only 7,945 being white. The colony is administered by a governor residing at Singapore, under whom are British resident councillors at Malacca and Penang. In 1867 the Straits Settlements were transferred from the government of India to the colonial office. The colony has a large and important transit trade through Singapore and Georgetown. Among its exports are tin, spices, gambier, rubber, copra, gum, tapioca, coffee, pineapples, sago and rattan. It imports rice, cotton and cotton goods, coal, opium, tobacco, petroleum, flour, fish and dress goods. The ports of the colony are all free; the shipping amounts to over 27,000,000 tons, and the trade to about \$497,000,000 annually. For further details see **PENANG**; **SINGAPORE**.

STRAKOSCH, strä'kôsh, Moritz, Austrian pianist and impresario: b. Lemberg, Poland, 1825; d. Paris, 8 Oct. 1887. He was educated at Vienna, and came to the United States in 1845, where he was a teacher and a concert pianist. In 1856 he began opera and concert managing, and introduced to the public Patti, Nilsson, and other famous singers. He also composed several pianoforte pieces, and 'Giovanna di Napoli,' an opera; and wrote 'Memoirs of an Impresario.'

STRALSUND, sträl'soond, capital of the government of Pomerania, and seaport on Strela Sound, 120 miles northwest of Berlin. The town stands on a promontory and presents a picturesque appearance with its wooden-gabled, antique buildings. The town-house (1311) contains an interesting collection of ancient relics from the island of Rügen and several churches, government-house, gymnasium, mint, arsenal, a large public library and charitable institutions. The principal manufactures are leather, sugar, starch, machinery, arc lights, bricks, furniture, oil and cards. There is considerable trade carried on from the port. This consists principally of grain, sugar, fish and malt. Stralsund was founded in 1209 by Saxons. It joined the Hanse Confederation and early attained commercial importance. It has repeatedly suffered severely from war. Wallenstein besieged it without success in the Thirty Years' War (1628). In 1678 Frederick William, the great elector of Brandenburg, took it after a severe bombardment. Politically it was a Swedish possession from 1648 to 1815 when it was annexed to Prussia. Population about 35,000.

STRAMONIUM. See **DATURA.**

STRANAHAN, strän'ä-an, James Samuel Thomas, American philanthropist: b. Peterboro, N. Y., 25 April 1808; d. Saratoga, N. Y., 3 Sept. 1898. He taught school for a year and then became a surveyor. In 1827 he went

to the Northwest to trade with the Indians, but this venture proving a failure he returned to Albany and entered the wool business. He founded the town of Florence, N. Y., in 1832 and in 1838 represented it in the assembly. In 1854 he was elected to Congress from Brooklyn to which he had removed in 1844. In 1860 he became park commissioner of Brooklyn. This office he held for 22 years, and during this time he controlled the expenditure of nearly \$9,000,000 for improvements. A bronze statue of him was unveiled at the entrance to Prospect Park 1891. He was actively engaged in the consolidation of New York, Kings, Queens and Richmond counties into the present city of New York.

STRANG, sträng, Lewis Clinton, American dramatic critic: b. Westfield, Mass., 4 Dec. 1869. He was graduated from the Boston University 1892. In 1894 he was assistant city editor and assistant in the dramatic department of the Boston *Journal* and in the fall of 1898 became dramatic editor. He has published 'Famous Actresses of the Day' (1899-1901); 'Famous Actors of the Day' (1899-1901); 'Prima Donnas and Soubrettes of Light Opera and Musical Comedy in America' (1900); 'Celebrated Comedians of Light Opera and Musical Comedy in America' (1900); 'Players and Plays of the Last Quarter Century' (1902).

STRANGE, stränj, Sir Robert, English engraver: b. in Pomona, one of the Orkney Isles, 14 July 1721; d. London, 5 July 1792. He studied law, attempted a seafaring life, then resolved to devote himself to painting. When the rebellion of 1745 broke out, he joined the forces of the Pretender and was present at the battle of Culloden. To conceal himself from pursuit he wandered for some time in the Highlands, and afterward ventured to Edinburgh, where he subsisted for some time by selling drawings which he had made of the chiefs of the rebellion. He afterward went to France, gained a prize for design at Rouen, and then resided for some time in Paris, where he studied engraving under Le Bas. In 1751 he settled in London, and became the founder of the English school of historical engraving. In 1760 he again visited the Continent and engraved pictures of many of the old masters. He was admitted member of the academies of Rome, Florence, Bologna, Parma and Paris, and on his return to England in 1787 was knighted. He followed the Italian masters, for the most part. His work is strong and individualistic; though it is sometimes defective in execution and especially drawing. Consult Blanc, Charles, 'L'Œuvre de Robert Strange' (Leipzig, 1848); Dennistoun, 'Memoirs of Sir Robert Strange' (London 1855).

STRANGE, Robert, American senator and lawyer: b. Virginia, 20 Sept. 1796; d. Fayetteville, N. C., 19 Feb. 1854. He was educated at Hampden-Sidney College and, after graduation, studied law and removed to Fayetteville, N. C. In 1821 he obtained election to house of commons and served till 1826, when he was elected judge of the Superior Court, from which he resigned to become member of the United States Senate. In 1840 he resigned in preference to carrying out the demands of his constituents. Returning to private practice he

was appointed solicitor of the Fifth Judicial District. He wrote a novel, 'Eoneguski; or the Cherokee Chief,' which was based on Indian legends of the Fayetteville region.

STRANGLES, a disease of the horse, ass, and mule, affecting especially young animals. It generally appears between the third and fifth years, and is preceded by cough, with a yellowish discharge from the nostril, and a considerable discharge of ropy fluid from the mouth. This is accompanied by the formation of a tumor under the jaw, beginning about the centre of the channel, and gradually filling the whole space. The disease is sometimes mistaken for glanders, but is easily distinguished by the fact that there is only a single tumor. The tumor gradually swells in the centre, becoming softer until it bursts, when a discharge of pus takes place. The cough then subsides, and the disease rapidly abates, although a considerable time often elapses before the animal recovers its strength. During the progress of the disease the animal suffers considerably from thirst, which it is unable to satisfy by drinking freely, the attempt to swallow bringing on a convulsive cough, from which the disease has its name. Treatment is chiefly directed toward advancing the development of the tumor, on the bursting of which convalescence depends. This is most effectively done by blistering or fomentation. When the swelling becomes soft on the top it should be freely lanced. When it is allowed to burst naturally an ulcer is formed which is very difficult of treatment. Consult Hutyra and Marek, 'Special Pathology and Therapeutics of the Disease of Domestic Animals' (Chicago 1912); Pearson, L., and others, 'Special Report on Diseases of the Horse' (Washington 1911).

STRANGULATION, violent constriction of the neck, involving such compression of the windpipe as to close the air-passages, prevent respiration, and finally cause death. In hanging, which sometimes produces strangulation, if much violence is used, death may be caused by direct injury to the upper part of the spinal cord (q.v.) from fracture or dislocation of the cervical vertebrae, or by syncope from shock; in such cases death must be almost instantaneous. If the constriction is so applied as to compress the great vessels in the neck and not the windpipe, death is due to coma, and is somewhat slower than in cases of asphyxia. If both vessels and windpipe are compressed, coma and asphyxia may both contribute to cause death. When suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; though many cases are recorded when after only a few minutes' suspension it has been found impossible to restore life. Moreover, if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe, death often taking place from secondary effects. It is believed that unconsciousness comes on very rapidly, and death takes place without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. Exposure to a free current of air, cold affusion, if the skin is warm, the application of ammonia

to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion, are good measures for the treatment of partial strangulation. They should be used if natural breathing is not at once resumed. From the post-mortem appearances together with circumstantial evidence, the medical practitioner is not unfrequently called upon to answer such medico-legal questions as: Was death caused by hanging, or was the body suspended after death? Was the strangulation the result of accident, homicide or suicide? In case of strangulation from other causes than that of hanging the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature the mark around the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging.

STRANGURY, an affection marked by scanty and painful micturition, with a frequent and irresistible desire to pass water. The urinary discharge is accompanied with scalding, cutting pains in the urethra, which sometimes extend to the bladder, the kidneys and the rectum. Strangury is a variety of retention of urine which may be caused by idiopathic urethrites, by gonorrhœa, or by such irritating substances as cantharides and oil of turpentine, or by gravel or calculus in the bladder. Besides removal of the cause, the following means are useful in treatment: The warm sitz-bath, or hot fomentations over the bladder; an injection of starch and tincture of opium, a wine-glassful of the former to a dram of the latter; and mild mucilaginous drinks of barley or rice water, which may be freely given to render the urine less irritating.

STRANSKY, Josef, American orchestral conductor: b. Humpoltz, Bohemia, 9 Sept. 1874. He was educated at the Prague Gymnasium and the universities of Prague, Vienna and Leipzig. He studied music under Judasohn, Fuchs and Bruckner. From 1897-1902 he was conductor at the Royal Opera at Prague, then at the Hamburg Opera and Symphony Concerts (1902-09). After directing operatic performances and concerts all over Europe he came to New York and has been conductor of the Philharmonic Society of New York since 1911.

STRAP-WORK, a style of architectural ornamentation or enrichment general in the 15th and 16th centuries and of which specimens exist executed as far back as the 11th century. It consists of a narrow fillet or band folded and crossed, and occasionally interlaced with another.

STRAPAROLA, strā'pa-rō'la, Giovanni Francesco, Italian novelist: b. Caravaggio, Italy, end 15th century; d. Venice, about 1557. His life is enveloped in doubt in spite of much research, but he wrote 'Canzoniere' which were edited in 1508 at Venice, besides a number of novels from popular traditions published under the title 'Piacevoli Notti' ('Facetious Nights') at Venice in 1550. The work has been reprinted. The Fairy Tales are the first work

of the kind in Italy's prose literature and it has proved the well from which many later writers have drawn their inspiration. From him are derived our 'Puss in Boots,' 'Fair Star,' 'Fortunio,' etc. Consult Rua, G., 'Le Piacevoli Notii di F. Straparola recherche' (Turin 1898); Borromi, C. 'M. G. F. Straparola da Caravaggio' (Pavia 1899).

STRAPPADO, a former military punishment, which consisted in having the hands of the offender tied behind his back, drawing him up by them to a certain elevation by a rope, and then suddenly letting him drop to within a certain distance of the ground.

STRASSBURG, Gottfried of. See **GOTTFRIED OF STRASSBURG**; and **TRISTAN UND ISOLDE**.

STRASSBURG, sträs'boorg, France, capital of Alsace-Lorraine, on the Ill, two miles west of the Rhine, on the French frontier, 350 miles southeast of Paris. It is ranked as a fortress of the first class. A massive inner rampart and 14 modern forts defend the city. It is cut by the Ill into several sections, and bears a quaint mediæval aspect. It is divided into four cantons; and owing to the fact that through it in normal times passes most of the traffic between France, Germany and Switzerland, from the Strassburg side, the city is of very considerable commercial importance.

The minster or cathedral, the product of four centuries (10th to 14th), is one of the grandest Gothic churches of the Continent. The tall spire (466 feet) rises from the western front, which is richly embellished with statues and bas-reliefs. The screen of double tracery is the work of Steinbach (13th century). The majestic interior is also richly decorated, and of vast dimensions. In the south transept stands a wonderful astronomical clock (14th century), renovated in 1839-42. It includes a perpetual calendar; the relative position and movements of the planets forming the solar system and many automatic figures which act at stated intervals. Other interesting features of the minster are the beautiful stained glass and rose-window (42 feet wide); choir-frescoes; and a pulpit of 1485. The Emperor William University (16th century) received a new foundation from the German emperor in 1872, the institution having been closed during the German occupation of Strassburg in 1870. It includes six faculties, has 172 teachers and an attendance of about 2,200 students. The library, which is one of the largest university collections in Germany, contains about 1,000,000 volumes, and 12,000 manuscripts. The main façade faces the imperial palace. Beyond the principal buildings are the various institutes for the exact sciences, the observatory, etc. Others are for the study of experimental physiology, pathology, pharmacy, surgery, eye-clinic, etc. The town also contains several good churches, Hotel-du-commerce, governor's palace, town-house, assembly-room, various museums and collections, benevolent institutions, excellent hospitals and a very large railway station.

Numerous public squares are embellished by statues, fountains and historical monuments, including busts of Goethe, Gutenberg and others.

The burgomaster, six associates and a council of 36 members constitute the governing body of the city. The most famous industry is the

making of *pâtés-de-foie-gras* (fat liver pies) whose annual export has sometimes reached \$500,000. Other industries comprise tobacco, liquor, leather goods, clothing, furniture, carpets, machinery, musical and surgical instruments, artificial flowers, gloves and the products of foundries, locomotive works, tobacco factories, tanneries, chemical works and piano factories. Transportation facilities by land and water are excellent. The town has always occupied an important military position and has been defended by fortifications of great strength and magnitude. Celts were the first inhabitants, replaced by Romans, and subsequently by Teutons, and about the 6th century Strassburg became a Frankish possession. This was the commencement of its German connection. Bishops and citizens were in perpetual strife in the early history of the town and the citizens finally obtained their independence (14th century). In 1681 it was seized by Louis XIV and became a province of France. In 1870 it was besieged and captured by the Germans and was ceded with Alsace and Lorraine to Germany. By the Peace Treaty of 1919 it again came under French control.

The population, which is about equally divided between Protestants and Roman Catholics, is 180,000. Consult Enting, Julius, 'Descriptive Guide to the City of Strassburg' (Strassburg 1905); Signouret, Raymond, 'Souvenirs du bombardement et de la capitulation de Strassburg . . . 1870' (Bayonne 1872).

STRATEGY, the science of directing, with promptitude, precision and clearness, masses of troops to gain possession of points of importance in military operations. Its object is to so direct these masses that upon reaching any designated point, the army shall have a better position than that held by the enemy, or shall have such a position as will force him to change his position, or shall be superior to him in numbers, or shall have some decided advantage over the enemy, in case of a conflict. In general, it may be divided into peace and war strategy, and the latter can be subdivided into that in the area of hostilities and that at home, comprising the mobilization, etc., of units and resources to support the forces at the front. There are two main principles which guide all warfare, whether on land or sea, and these are concentration and the initiative. *Concentration* consists in so disposing the forces that they may be superior to the enemy at the critical point and moment. A belligerent secures the *initiative* when he compels the enemy to conform to his movements, to accept battle on his own terms, and that means when his concentration is completed. The value of the initiative is that it enables the belligerent securing it to take advantage of concentration, and *strategy* is the art by which a belligerent brings about this condition of affairs. The initiative must not be confounded with the offensive, they are not synonymous terms.

There is a close relationship between strategy and tactics. Strategy is, in a peculiar sense, the science of generals in command of armies; while tactics in all its ramifications, from the elementary drill of the soldier to orders of battle, from the bivouac of an outpost to the encampment of an army, now belongs to officers of all grades. Yet with these marked dif-

ferences, it is sheer pedantry to pretend to define the precise limits of these two prominent branches of the military art, as they present a multitude of exceptions in which they approach and run into each other. Tactics, if we restrict its meaning to the evolutions and manoeuvres of troops on the field of battle, may be taught with mathematical exactness, because every movement is accurately prescribed, and the more so the lower we descend the scale of this branch of military knowledge. But this is far from being true of strategy, because in the calculations involved in its operations, a great many considerations enter which do not admit of exact computation, and upon which success or failure essentially depend; as time, the character of the roads over which the army has to move, the nature of the obstacles which lie between it and the enemy, the moral qualities and activity of the enemy's forces, etc.

In a mountainous country, the strategical points, although few in number, are generally very prominent. The junction of several valleys, or roads along the crests of several ridges, would naturally be of great value to an army occupying it, as the forces might operate in any one of the valleys or along any of the roads with an equal facility, while the enemy, once committed to one line, could not change to another without great labor and loss of time, necessitated by the retrograde movement resulting from the difficulty of crossing the intervening spurs or valleys. In the campaign of 1796-97, in Italy, Bonaparte, by causing the redoubt which closed the pass of the Montenotte to be occupied by 1,200 men, was able to interpose his army between the armies of the allies—Austrians and Sardinians—and whip them in detail. At this time the allies, numbering about 60,000 men, were operating in three columns by three roads separated by very difficult mountainous country. Bonaparte, with about 30,000 men, holding the middle road, the pass of the Montenotte, very successfully accomplished his plan of attacking in succession the columns of the enemy. The campaign was thus decided from its inception, and the redoubt of Montenotte, seconded by a small and brave garrison had great influence upon the final result. The capital city of a country is usually a very important strategical point. This may proceed, not from its influence on the military operations of a campaign or from its position, but from the fact that it is the seat of the government the occupation of which by the enemy may have a lasting and damaging effect in a political point of view. During the American Civil War great importance was attached to the capture of the city of Richmond, and all the campaigns of the army of the Potomac were made with that city as the objective point, with the idea that its fall would put an end to the war. This was undoubtedly too much to expect, for the bulwark of the rebellion was not the city of Richmond, but the Confederate armies, and their capture or overwhelming defeat was necessary before the fall of the city would be a decisive cause of the close of the war. The supplies and reinforcements of the Confederate army were nearly all drawn from the States south of Virginia, and as long as the avenues of supply remained intact the cohesion of the army was assured and it remained a menacing force.

Movements in war, whether offensive or defensive, must always be based on calculation of time and distance. In an offensive war the operations are vaster, the conditions more variable and the elements of the calculation more uncertain. In a military point of view, the offensive has its good and its bad side. Strategically an invasion leads to deep lines of operation, which are always dangerous in a hostile country. All the obstacles in the enemy's country, the mountains, rivers, defiles and forts, are favorable for defense; while the inhabitants and authorities of the country, so far from being the instruments of the invading army, are generally hostile. However, if success be obtained, the enemy is struck in a vital point; he is deprived of his resources and compelled to seek a speedy termination of the contest. For a single operation, which we call taking the *initiative*, the offensive is almost always advantageous, particularly in strategy. Indeed, if the art of war consists in throwing the masses upon the decisive points, to do this it will be necessary to take the initiative. The attacking party knows what he is doing and what he desires to do; he leads his masses to the point where he desires to strike. Tactically, the *offensive* also possesses advantages, but they are less positive since, the operations being upon a limited field, the party taking the initiative cannot hide them from the enemy, who may detect his designs, and by the aid of good reserves cause them to fail. Whatever advantages may be expected either politically or strategically from the offensive, it may not be possible to maintain it exclusively throughout the war; for a campaign offensive in the beginning may become defensive before it ends. The offensive confers, at the outset, the power of concentrating on the flank or centre of the enemy's line of defense, and so turning or breaking it. The defender must either oppose the enemy with an inferior force at first, or abandon territory in order to assemble his forces at some point further back. On the other hand, offensive war demands great resources, and success itself, if not absolute and decisive, entails fresh difficulties on the invader. And when he has penetrated very far within the defender's territory, the situations of the antagonists differ greatly, inasmuch as the army on the offensive is bound to its base, be that base wide or narrow, while the defensive forces may base themselves on any portion of the territory which will supply them and which their front protects. It is evident that when one belligerent power feels secure behind an unassailable frontier, and holds many issues into the enemy's territory, either by command of the sea or otherwise, it can assemble its forces unknown to its antagonists upon some point selected by itself, from whence to make an eruption into the theatre of war. And if the belligerents be divided only by a frontier line—a river such as the Rhine, or a mountain range such as the Alps—the army that passes it will nearly always find itself immensely superior to the forces that can immediately interpose.

Battles have been stated by some writers to be the chief and deciding features of war. This assertion is not strictly true, as armies have been destroyed by strategic operations without

the occurrence of pitched battles, by a succession of inconsiderable affairs. It is also true that a complete and decided victory may give rise to results of the same character when there have been no grand strategic combinations. The results of a battle generally depend upon a union of causes which are not always within the scope of the military art; the nature of the order of battle adopted, the great or less wisdom displayed in the plan of the battle, as well as the manner of carrying out its details, the more or less loyal and enlightened co-operation of the officers subordinate to the commander-in-chief, the cause of the contest, the proportions and quality of the troops, their greater or less enthusiasm, superiority on one side or the other in artillery or cavalry, and the manner of handling these arms; but it is the *morale* of armies, as well as of nations, more than anything else, which makes victories and their results decisive. When the march of an army has been so conducted, that, when it meets the enemy on the field of battle, it has a decided advantage over him, the battle which follows will usually be more decisive than in the contrary case. A single battle well fought under the foregoing condition has frequently been decisive of the whole campaign, and even of the war. The battle of Jena gave Napoleon advantages, which vigorously followed up in the manner so peculiar to him, soon placed the kingdom of Prussia at his feet, and left him free to turn his attention to the Russians.

Tactical and strategical consideration both enter into the problem of determining the point of attack; the consideration which will govern in any particular case will depend upon the results which are expected to follow the defeat of the enemy, or the risks to be run in achieving these results. The tactical considerations relate to the advantages which can be gained on the field of battle; and the strategical to the consequences of victory. The strategical

FIG. 1.

conditions are more important than the tactical, unless the difficulties of the ground are too great, and the results expected to follow do not justify the risks to be taken. Let the army *P* in Fig. 1, find the enemy in the position *AB*, with one flank resting on a hill and the other on a river, with an impossible marsh in front. The point *A* is both the strategical and tactical point of attack; for its capture would command the field of battle, force the enemy from his line of retreat, *xy*, and throw him

back on the impassable obstacle opposite the left flank, *AC*; with the right reinforced it would be a better position for the assailed to take, as in this case an attack at *A* would compel the assailant to fight with an obstacle at his back, and an attack at *C* would give the assailed the full benefit of the height. The position *AC* is also objectionable, as it presents a salient *D*, always a weak point in a line, because it renders both faces liable to be enfiladed. Suppose an army, acting on the defensive, to have the position *XY*, Fig. 2; its right uncovered, and its left resting on an impassable obstacle. The strategical point of attack is *Y*; for, if the left is forced back, the line of retreat *AB* is exposed. But the selection of *Y* as the point of attack forces the assailant to fight with his back to the obstacle *Z*, which would be very dangerous unless greatly superior to the enemy. Rather *X* select as the point of attack, and depend upon vigorous fighting and pursuit for

FIG. 2.

great results. Combined attacks, like combined marches, cannot be relied upon for success. They should only be undertaken when the natural features of the country are such that the enemy can be easily checked if he attempts to make a counter-attack, and when the preliminary movements of the troops are concealed from his view. When the features of the country are such that the detachments can, by taking up naturally strong positions, hold the enemy in check, the main body can operate with safety against the flank; for, in case of repulse, its main line of retreat would not be compromised. Much depends upon the character of the opposing general; if he be alert and always ready to act promptly and vigorously, any extended movements would be dangerous, although it might under other circumstances be successfully carried out. Movements may be made with troops that are superior in numbers or in discipline, which would be very rash when the opposing forces are nearly equal, or the commanders of the same capacity. A careful reconnaissance is important in both tactical and strategical operations. A general reconnaissance has for its object the obtaining of detailed and accurate information of countries and their armies that will be of assistance in case of war. It comprises within its scope our own as well as other countries, for the data obtained may be useful in prosecuting military studies, and as an aid to a general in drawing up his plan of operations, which includes the

movements of troops necessary for concentration as well as their employment after this has been accomplished and they are ready to meet the enemy. Tables of statistics, giving population, manufactures, industries and information concerning the roads, railroads, canals, rivers, important improvements, etc.; geographies, general and military; reports of various kinds, etc., will all be found of great assistance in compiling the required information. But, however complete and exhaustive these sources of information may be, officers of the army should frequently be sent to different countries to examine and report not only upon their military systems, but upon any subject which may become important in a military point of view. This method not only serves to retain possession of

arms, as by its assistance, woods or other suspicious places, within range, could be effectively examined or cleared of the enemy's presence, without the necessity of a close approach. Guns can also cause the withdrawal of parties of the enemy from small defensive positions by acting on their flank.

From the point of view of most recent military strategy, America's greatest contribution to the successful outcome of the European War was the hotly-contested battle of the Meuse, which resulted in cutting the main artery of the German supply system. Up to the middle of September 1918 the Germans were able to operate unmolested the Sedan-Mezières railway running parallel to the front and furnishing a base of supply for the whole line from

FIG. 3.—Illustrating the value of Land-and-Sea Operations and combined expeditions directed against the Sea-power of the enemy.

much that might be of great utility in planning military operations, but it enables officers to gain personal experience of peoples and their customs, which might be invaluable to them and to their country, in the event of war. *Special* reconnaissances are made with reference to the actual military situation at the time, and a report of them is usually made at once, frequently upon the spot. They are known as *topographical* and *armed* reconnaissances, the latter being usually termed a *patrol*, *scout*, or *secret reconnaissance*. A reconnaissance in force is generally made just before a battle, for the purpose of forcing the enemy to develop his strength and dispositions.

The addition of infantry gives to reconnoitering parties a strength and power of resistance which cavalry can never attain by itself. The employment of artillery tends toward a similar end and the especial mobility of horse artillery renders it most appropriate for such service. Artillery is nevertheless seldom added to an ordinary reconnoitering party, its use being generally confined to a reconnaissance in force, or a special reconnaissance. But, although guns are not much employed upon this kind of duty, there may still be occasions where artillery would prove a useful addition to the other

Valenciennes to Metz. To cut this supply line at both ends and force withdrawal or capture on this entire front the British attacked in the north. The first few days of fighting yielded considerable gains. Fully conscious of the gravity of the situation, the enemy threw in division after division of fresh troops, and during the ensuing weeks occurred the bitterest fighting in which American troops took part. The second week of October practically all available units—about 28 divisions—were in the line. Progress could be made only a few yards at a time, but the continued hammering finally wore out the resistance of the enemy forces and the American troops broke through. Day after day steady gains were made up the west bank of the Meuse, until, on 7 November, the United States forces entered the outskirts of Sedan and definitely cut the German supply line. A day later the French forces came up on the left flank. The meeting of French and American troops on this historic spot signaled the defeat of the German arms, a defeat as decisive and humiliating as that forced upon France 47 years before at the same spot. If there had been questions before as to the acceptance of the armistice terms, the allied advance culminating in this meeting at Sedan

left no choice in the matter. In the final campaign of the war American troops thus played a part in a triumph which was beyond all praise.

The actual success of operations in war must primarily rest on the action of small bodies; good previous strategical movements, a correct formation of the order of battle, a proper selection of the points to be attacked, will make the success when obtained of far greater importance; but the actual success must ultimately depend on the correct handling of small bodies of men. This is one of the features of modern fighting and one which must be carefully considered. A battle under existing circumstances is a series of small battles or fights in which bodies of troops, perhaps not greater than a brigade, are engaged, and each of these bodies must be tactically complete, must work for one object, and seek to carry one point. It has been said that for the future no direct attack can possibly be made on troops occupying a position and that attacks must be made on the flanks: but recent experience shows that attacks on the flanks, unless supported by a strong front attack, can always be met and defeated. The strategy of the recent European War was largely influenced by the enormous frontages successfully held. Relying on the defensive power of modern weapons, great extensions of lines were made for the purpose of resting flanks on secure obstacles. When a line is persistently and sufficiently battered, a retirement becomes necessary. This is depressing to the morale of the troops and even in a voluntary retirement the losses in men and matériel are unduly large. Therefore, a retirement should be avoided when possible and should be accompanied by a contraction of the front, either closing in on the centre leaving two exposed flanks, or to one side leaving one exposed flank. It would appear that whatever advantage accrues from shortening the front would accrue equally to both sides. The advantage of a short front lies in the fact that it takes a greater preponderance of force to break a front strongly held than one weakly held. Further, the opportunity for manoeuvre is restricted by a narrow front. Wellington's withdrawal to the lines of Torres Vedras is a classical example of shortening front by retirement. The European War furnished one example of the successful shortening of a line in the Allied withdrawal to the Salonika position.

Numerous wars have demonstrated the strategical principles of concentration of effort, importance of initiative, value of surprise and necessity for unrelenting pressure on a beaten enemy, and they have been demonstrated again in the European War. But operations of detached forces against the enemy's communications, of which there are many examples in former wars, seldom occurred in the late war. Such operations depend on rapid and resolute execution and close co-operation between the divided forces. Operations against communications are hardly practicable under modern war conditions with the huge forces and continuous fronts involved. General Maude used this method against the Turks at Kut el Amara, but it was not used in the great theatres in Europe.

The attack at Gallipoli can hardly be classed as an operation against communications, al-

though undertaken partly with the object of cutting off the Turks from their German allies. The operations demonstrated the futility of employing inadequate forces, for the French and British gained no advantage from this employment of a dozen divisions assisted by naval forces. The operations of the German submarines were aimed at the British sea communications. The Allies could not get at the German fleet because of mine fields and coast defenses and the submarines caused the employment of considerable naval forces against them. It is thus advantageous to menace the enemy's communications.

The European War may be termed a *war of positions*. The French and German armies, after marching toward one another, came into collision. The French army, led away by war-like enthusiasm, threw itself without protection against the cannon, the machine guns and the trenches of the German army; and left thousands of dead on the first battlefields. It retreated. At the Marne it offered a superb resistance, once more sacrificing thousands of lives. Then the German army retreated in its turn, but established itself solidly on the Aisne, protected by previously prepared trenches. The French army dug in opposite. Each adversary, finding himself unable to dislodge the other by direct assault, tried to outflank him. Thereupon began the famous "race to the sea"; the two armies stretched out trenches, face to face with one another, all the way between two impassable obstacles, the sea and Switzerland. The European War, much more than any preceding war, may be termed a war of *matériel*. An offensive, even a partial one, requires not only an enormous supply of cannon, munitions and machines, but also factories capable of producing them, railroads and highways sufficient for their circulation, ships, cars and trucks in plenty to bring them up and special depots for their storage. The European War may also be termed a war of *attrition*. In previous wars professional soldiers fought with their own resources and settled between them the quarrels of nations. To-day it is the nations themselves, with all their forces, human and material, that take part in the struggle; they fight till one of the adversaries is completely exhausted. Thus, attrition, which applies to both men and *matériel*, is a factor which is bound to enter largely into final results. Attrition in men is irreparable; attrition in *matériel* can be offset by greater activity in the factories, but these factories must be sufficiently well equipped to meet the needs of the army under all circumstances. Attrition in men is not very dangerous for countries which have sufficient human reserves, such as Russia, nor yet for those like France and Great Britain, which can draw on their colonies. On the other hand, it is highly dangerous for countries like those of Central Europe, where human resources are strictly limited. For these countries there will inevitably come a moment when it will be impossible to find enough men to hold the front and to run the factories.

During the European War numerous actions and things occurred to change the significance attached in certain quarters to the word *strategy*. Its meaning may be better grasped if illustrated, rather than defined. Hamley, a well-known English writer, claims

that "the theatre of war is the province of strategy, the field of battle is the province of tactics." Clausewitz considered that "tactics is the employment of troops for the object of the fight; strategy is the adaptation of fighting for the object of the war." Derrécagaix, a French author, observed that "the combinations of strategy are governed by immutable principles, while tactics includes operations which are subject to modification as improvements are made in war material." This, however, does not furnish the whole truth, as certain principles of tactics, such as concentration of force, the value of surprise and of superiority of fire, are as constant as those of strategy. At the commencement of the European War, the word strategy at once attained high popularity,

roul of Bulgaria. This was due to the reinforcement of the Allies by Venizelo's new Greek army, though this army was not used on the part of the field where the chief rupture was effected. Contributing causes were the deterioration of the *morale* of the Bulgarian army and people and the skill with which General D'Espérey chose the time and place for the chief attack. The Allied intelligence was thorough in its functions. (See Fig. 4.).

Considering the great advances in aeronautics, radio-telegraphy and gunnery it is apparent that the true way to security is *strategic surprise*, that is to say, it is possible for the enemy to attack when we are least prepared to cope with him and by the skilful use of *inner lines*. The British in the Northwest were

FIG. 4.—The American Sector and Strategic Movements near the Boundary dividing French from German Lorraine.

while the word tactics was neglected. Strategy, then, soon came to be the term applied to every operation of war, large and small. A reconnoitering patrol which had carried out its duties smartly was said to have displayed fine strategy, the clever concealment of a machine gun was cunning strategy, etc., etc. Mont Kemmel, a small hill in French Flanders, became a strategical key point, and it has been stated on the highest authority that Vimy Ridge, which was captured in 1917, has proved to be a feature of the highest strategic importance. Formerly tactical would have been the adjective used in these descriptions, now it is strategical.

In the course of the European War, 1914-18, there developed many strategic mysteries—the Russian success in East Prussia, followed by the defeat at Tannenberg; the sudden arrest and defeat of the Germans on the Marne; Mackensen's overwhelming blow against the Russians when the latter were threatening to overrun Hungary in the early part of 1915; and many others. The easiest of these strategic mysteries to explain is the final and rapid

very efficiently assisted by the French to keep up their priceless communications with their sea bases and held back for months hundreds of thousands of the invaders and at last the converging Entente armies, in November, 1918, brought about the completest collapse of Germany since the days of Julius Cæsar. (Fig. 4). Profiting by a study of the blunders of 1870, we may add to Napoleon's maxims about readiness these two principles: (a) In strategy, as in everything else, the jump into the unknown is the reverse of desirable, or reasonably one has no right to substitute for the hard facts of reality, which should always be sought for, the creations of imagination and hypothesis. On these known facts alone a reasonable operation can be based. (b) In any case, not merely in strategy, but in fact, one ought not to undertake a manœuvre which causes dispersion without being guaranteed the possibility of being able in time and place to change it into a concentrated plan.

Another lesson enforced on all students of war alike by Napoleon, Moltke and Foch is

that knowledge, a disciplined understanding, a cultivated memory and all the resources of science, art, invention, as well as readiness, judgment and initiative are more important to the general than to surgeons, engineers, etc. The strategist of to-day declares that ignorance and carelessness are intolerable in military men and that military skill is priceless. The mind is the army. The general is the soul, the nerve centre, the brains of the army. (See TACTICS). Consult Altham, 'The Principles of War' (London 1914); Aston, 'Sea, Land and Air Strategy' (ib. 1914); Clausewitz, 'Germany's War Mania' (ib. 1914); Derrecagaix, 'Modern War' (Washington 1890); Dufour, 'Strategy and Tactics' (New York 1864); Dickman, 'Notes on the German Army' (United States Infantry and Cavalry School, Fort Leavenworth 1897); Mahan, 'Mahan on Naval Warfare' (Boston 1918); Wagner, 'Organization and Tactics' (London 1895).

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

STRATEMEYER, strät'-ē-mī-ēr, Edward, "CAPT. RALPH BONEHILL," "ARTHUR M. WINFIELD," American writer of juvenile fiction: b. Elizabeth, N. J., 4 Oct. 1862. He was editor of *Good News*, *Young People of America*, and *Bright Days*. He has published over 100 volumes, including 'Old Glory Series' (1898-1902); 'Dave Porter Series' (1905-16); 'Flag and Frontier Series' (1899-1907); 'Rover Boys Series' (1899-1917); 'American Boys Life of William McKinley' (1901); 'American Boys Life of Theodore Roosevelt' (1904); 'Putnam Hall Series' (1905-12).

STRATFORD, Canada, city and county-seat of Perth County, Ontario, on the Avon River, and on the Grand Trunk Railway system; 88 miles west-southwest of Toronto, and 80 miles northeast of Sarnia. The chief industrial establishments are the railway repair shops, saw, planing, flour and woolen mills, foundries, and manufactories of chairs, carriages, bricks, shoes, biscuits and confectionery, cigars and machinery. There are five banks. The city contains a general hospital, house of refuge, boys' home, numerous churches, a public library, city hall and courthouse. For educational purposes there are the Provincial Normal School and several public and separate schools. Stratford was first settled in 1831, became a borough in 1855, and was incorporated as a city in 1885. Its government is vested in a mayor and a council of 10 aldermen elected annually. Pop. about 20,000.

STRATFORD, Conn., city in Stratford township, Fairfield County, on the west bank of the Housatonic River, about two miles from its mouth, and on the New York, New Haven and Hartford Railroad. It is three miles from Bridgeport and is bounded on the south by the Long Island Sound. Its manufactures consist of paints, silverware, brassware, etc.

STRATFORD DE RADCLIFFE. See CANNING, STRATFORD.

STRATFORD-UPON-AVON, ā'vón, England, a market-town and municipal borough in Warwickshire, 94 miles northwest of London, on the Avon. The town comprises an old and a new section, but its chief points of

interest are associated with the name and life of Shakespeare. In Henley street stands an unpretentious one-story gabled wooden house, where he was born, and which now belongs to the British government. The house where he died was torn down in 1759. The parish church of Holy Trinity, late Gothic, dates from the 15th century, and Shakespeare's remains were interred in its chancel. There stands to-day a monument and bust erected to his memory.

Anne Hathaway also is buried in this church. A small memorial hall and the interior of the town-hall are dedicated to Shakespeare's memory. The town has a fine guild-hall, a new public library, rich in Shakespeareana (1905), art gallery with many Shakespearean paintings, market-house, corn exchange, almshouses, churches for Dissenting denominations, a hospital for infectious diseases, a new school for technical education, public schools, the fine Shakespeare memorial theatre, and the Shakespeare fountain, erected by George W. Childs, the well-known American. The town-hall contains Garrick's portrait by Gainsborough. At Wilmcote near by is the cottage of his mother and at Shottery, also in the neighborhood, that of his wife, Anne Hathaway. The visitors to the town are its chief source of wealth. The tercentenary of Shakespeare's death was celebrated with great *éclat* in 1916. In recent years, through the efforts of Marie Corelli, and a few who support her artistic tastes great changes have been wrought in the ancient town. Old houses with plastered walls, which were eyesores to the visitors and residents alike, have been stripped of their outward ugliness, to reveal the quaint, picturesque tudor architecture of Shakespeare's time. Wherever it has been possible the early appearance of the buildings has been restored, and the effect has been a most remarkable transformation and restoration of the place as Shakespeare knew it. The ancient "sword of state," which hangs in Shakespeare's birthplace, was removed from its scabbard in August 1914, as an official notice that England was at war. The people say tradition forbids them to sheathe the old sword carried by Shakespeare's father when he was high bailiff in 1568-69, until England is again at peace. The town owns the gas and water-works, and has constructed an excellent system of main drainage and works for sewage disposal. Pop. 8,531. Consult Lee, Sir Sidney, 'Stratford-on-Avon' (London 1890); Savage, 'The Registers of Stratford-on-Avon' (ib. 1898); Stopes, C. C., 'Shakespeare's Environment' (ib. 1915).

STRATHCONA, Canada, a town of Alberta, Northwest Territories, on the south bank of the north Saskatchewan River, opposite Edmonton, with which it is connected by a steel bridge. It is the northern terminus of the Calgary and Edmonton branch of the Canadian Pacific Railway, and with Edmonton (q.v.), it is the transportation centre for the grain, cattle, and other industries of northern Alberta. There are in the town some manufactures, among them flour, oatmeal, butter and cheese, lumber, foundry products, boats and dredges. Coal is mined in the vicinity. Strathcona has churches, schools, banks and weekly newspapers. Pop. about 8,000.

STRATHCONA AND MOUNT ROYAL, Donald Alexander Smith, 1st BARON, Canadian statesman: b. Forres, Morayshire, Scotland, 1820; d. 1914. After education in the preparatory schools of his native country, he went to Canada in the employ of the Hudson's Bay Company in 1838, where he spent 13 years on the Labrador coast, after which he was stationed in the great Northwest, where he was promoted to be a chief factor. Later he was named resident governor and chief commissioner of the company in Canada. He first became prominent in public life when appointed special commissioner by the Dominion government to investigate the insurrection under Louis Riel in 1869 at the Red River settlement. In 1870 he was elected to the Manitoba legislature as member for Winnipeg on the organization of that province, and later on to the Canadian House of Commons for Selkirk. But owing to the passage of a law against dual representation he resigned from the local house in 1874. He was also appointed a member of the Northwest Territorial Council. In 1880 he lost his seat in the Canadian House. He re-entered public life in 1887, as a member of the Dominion House, remaining there till 1896, when he was appointed to represent the Dominion of Canada in London as High Commissioner, a position he held until his death. At the beginning of his political career he supported Sir John Macdonald, the conservative leader; but at the time of the "Pacific Scandal" in 1873, he transferred his support to the Liberals. After 1878 he gave Macdonald independent support in his fiscal and railway policy. He was actively connected with many industrial and commercial undertakings, but his name is particularly connected with railway development in Canada. The organization and success of the Canadian Pacific Railway is due largely to him. In 1886 he was knighted and in 1897 raised to the peerage as Baron Strathcona and Mount Royal, and he was the recipient of many other favors and honors, among them degrees from a dozen universities. He was president of the Bank of Montreal (1887), governor of Fraser Institute, and governor and chancellor of McGill University (1898) and of the University of Aberdeen (1903) and also Lord Rector of the latter institution. He was prominently connected with a long list of educational, religious and financial institutions. Lord Strathcona was a very liberal and appreciative patron of art and his art collection is said to have been the largest and most varied possessed by any one person in Canada. His benefactions to education were extensive and widely distributed. He endowed the Royal Victoria College, Montreal, for the higher education of women; gave over \$1,000,000 to McGill University; about the same amount to the Royal Victoria Hospital, Montreal; and he endowed chairs in numerous colleges. He gave \$1,000,000 to the King Edward Hospital fund and was a liberal helper of other similar institutions.

STRATHROY, Canada, town and outport of Ontario, County of Middlesex, on the River Sydenham and on the Grand Trunk Railroad. It is 20 miles west of London and has a collegiate institute and armory, a cannery, brewery and manufactures of iron castings, stoves, etc. Pop. 2,823.

STRATIFICATION, layering in sedimentary rocks. Such layering is usually produced by changes in the character of the sediments being deposited. These may be changes in the composition of the material, as when a clay is laid down on top of a sand; or they may be changes in the size of particles, as when a fine sand is covered by coarse sand. A cross section of any sand bar along a creek bed will illustrate the process. On a small scale it is produced by daily or seasonal variations in the carrying power of a stream or streams. On a larger scale in the ocean it is produced by depression or uplift, so that areas near shore which received coarse material such as sand are brought out into the deeper water and receive fine muds or oozes, and the reverse. Sometimes, after a layer of material has been deposited, there is an interval during which the material partly solidifies before the next layer is formed. This will produce a plane of parting or bedding plane. See **FORMATION**; **STRATUM**, etc.

STRATIGRAPHY, that branch of geology that deals with the arrangement, age and succession of rock strata, mainly as revealed by the contained fossils. See **GEOLOGY**, section devoted to *Stratigraphy*.

STRATTON, strät'n, Charles Sherwood ("Tom Thumb"), American dwarf: b. Bridgeport, Conn., 4 Jan. 1838; d. Middleborough, Mass., 15 July 1883. He was born of normal parents, and showed no peculiarity until the age of seven months, when he ceased to grow in height. In 1842 he was taken by his mother to P. T. Barnum, and at that time was 28 inches in height, and weighed a little more than 15 pounds, though he later increased in size. He was perfectly proportioned, active and intelligent; and his exhibitions proved a great success. In 1854 he was taken to England by Barnum and presented to the queen and royal family, and later to Paris, everywhere receiving marked attentions. In 1863 he was married to Lavinia Warren, a dwarf girl, and together they traveled widely and gave exhibitions.

STRATUM, a unit of classification in the scale of geological formations. It is a section of any geological series, composed throughout of the same material as shale, limestone, sandstone, coal, etc. The stratum may be subdivided into beds of which there may be many in a thick stratum. Beds, where very thin, are known as laminæ, and the sediments are said to be laminated. A stratum indicates a uniform condition of decomposition during its formation.

STRAUS, strows, Isidor, American merchant and communal worker: b. Rhenish Bavaria, 6 Feb. 1845; d. with his wife in the Titanic disaster, 1912. He arrived in America in his ninth year and settled in Tolbolton, Ga., and was preparing to enter the West Point Academy, when the Civil War intervened. In 1865 he removed to New York, where his father founded the firm of L. Straus and Sons a year later. In 1888 he and his brother Nathan associated themselves with R. H. Macy and Company of New York, and in 1893 with Abraham and Straus of Brooklyn. Always interested in tariff and currency reform, he was elected 3 Jan. 1894 from the 15th District, New York, to fill the unexpired term of A. P. Fitch

to Congress. He was president of 'The Educational Alliance' and a prominent worker in charitable and educational movements, and was very much interested in civil service reform and the general extension of education. He declined the portfolio of Postmaster-General which was offered him by President Cleveland.

STRAUS, Nathan, American merchant and philanthropist: b. Rhenish Bavaria, 31 Jan. 1848, brother of Oscar Solomon and Isidor Straus (qq.v.). He came to the United States in 1854 with his family who settled in Tolbolton, Ga., where he attended school. He afterward went to New York and graduated at Packard's Business College. He joined his father in the firm of L. Straus and Sons, importing pottery and glassware; from 1888 was partner in R. H. Macy and Company, New York; from 1892 of Abraham and Straus, Brooklyn, and retired in 1914 to devote his time to charity. In 1898, during the Spanish-American War, he donated an ice plant to Santiago. He originated, in 1890, and has since maintained at his own expense, a system of distribution of pasteurized milk to poor of New York City, which, statistics of health department show, is saving many thousands of lives annually. He also originated and maintained a system of depots for distribution of coal to poor of New York in winter; and in the panic of the winter 1893-94, maintained a system of lodging houses for poor and homeless. He was appointed by President Taft sole United States delegate to the International Congress for Protection of Infants, Berlin, 1911, also delegate to the Tuberculosis Congress, Rome, Italy, 1912. In 1912 he established soup kitchens in Jerusalem for relief of destitute, and a health bureau for the elimination of conditions causing malaria, in Palestine. During winter of 1914-15 served for the unemployed 1,135,731 penny meals from his milk depots in New York City, was chief contributor in sending a food ship to war sufferers in Palestine, and extended his Jerusalem health bureau to care for sick and wounded, under auspices of the Palestine government. He has delivered numerous addresses on pasteurization and published 'Disease in Milk, the Remedy, Pasteurization' (1913).

STRAUS, Oscar Solomon, American merchant and diplomat, brother of Isidor and Nathan Straus (qq.v.); b. Otterberg, Bavaria, 23 Dec. 1850. A resident of Georgia from 1854 to 1865, he was graduated from Columbia University in 1871 and from its law school in 1873. He engaged in mercantile life for a time with his father's firm, but found leisure for literary and educational work. He was appointed United States Minister to Turkey 1887-98 and 1898-1900, in 1902, a member of the Permanent Court of International Arbitration at The Hague and in 1906 he became Secretary of Commerce and Labor in the Roosevelt Cabinet. He was Ambassador to Turkey (1909-10); and Progressive candidate for governor of New York State; and he arbitrated the dispute between the engineers and managers of the eastern railroads (1914). The following year he became chairman of the public service commission of New York State. He is president of the American Jewish Historical Society and has published 'The Origin of Republican Form of Government of the United States' (1886);

'Roger Williams' (1894); 'The Development of Religious Liberty in the United States' (1896); 'Reform in the Consular Service' (1897); 'United States Doctrine of Citizenship' (1901); 'Our Diplomacy with Reference to our Foreign Service' (1902); 'The American Spirit' (1913).

STRAUSS, David Friedrich, German theologian: b. Ludwigsburg, Württemberg, 27 Jan. 1808; d. there, 8 Feb. 1874. He studied in Tübingen University; became assistant to a country clergyman in 1830; was appointed temporary professor in the seminary at Maulbronn; resigned this position and went to Berlin in 1831 to study under Schleiermacher and Hegel. He returned to Tübingen and lectured on logic and philosophy; and published in 1835 his famous 'Life of Jesus,' in which he attempted to prove that the gospel narratives had a mythical origin and growth. To his numerous critics he replied in 'Streitschriften' and 'Zwei friedliche Blätter.' Appointed in 1839 to the chair of dogmatic theology in Zürich he was prevented from entering upon his duties by a storm of popular indignation, but received a small pension in recompense. In 1848 he was elected a member of the Württemberg Diet; a position he resigned because he found it uncongenial. His subsequent writings were 'Christliche Glaubenslehre' (1839-41); 'Life of Schubart' (1849); 'Life of Christian Märklin' (1851); 'Life of Ulrich von Hutten' (1858-60); 'Leben Jesu für das Deutsche Volk' ('Life of Jesus for the German People,' 1877); 'Der Christus des Glaubens und der Jesus der Geschichte' ('The Christ of Faith and the Jesus of History,' 1865), and 'Der alte und der neue Glaube' ('The Old and the New Faith,' 1872), in which he defines his final attitude to Christianity, that being now entirely hostile. His more important works have been translated into English. He also gave much attention to literary criticism and wrote critical biographies of Schubart.

STRAUSS, Eduard, Austrian composer of dance music, son of Johann Strauss: b. 1835; d. Vienna, 29 Dec. 1916. He was the composer of more than 200 pieces of dance music, being almost as prolific a composer as his famous father, who wrote 246 pieces of dance music and innumerable operettas. His brother Joseph, known as the "Waltz King," was the composer of nearly 300 waltz pieces. In 1870 Eduard Strauss became prominent in the musical world when he was made conductor of the court balls in Saint Petersburg. Later he made many tours with his own orchestra throughout Europe and in 1892 and 1901-02 visited America. He made his home in Vienna, where in the summer he played at the Volksgarten and in the winter at the Gesellschaft der Musikfreunde.

STRAUSS, Emil, German novelist: b. Pforzheim, 31 Jan. 1866. He attended gymnasium at Pforzheim, Mannheim, Karlsruhe and Cologne and the universities of Freiburg, Lausanne and Berlin. At Freiburg, where his studies were in philosophy, literature and political economy, he formed a close friendship with Emil Gött (1864-1908), with whom he settled successively in various country places in order that they might live the life of common peasants

together (Ueberlingen, Emmisheim, Kappelrode). He is at present living at Hellerau, a suburb of Dresden. His favorite pursuit in literature is the detailed study of childhood and adolescence, resulting in the production of a number of fine psychological studies, of which the best are 'Der Engelwirt, eine Schwabengeschichte' (Berlin 1900; 4th ed., 1910) and 'Freund Hein, eine Lebensgeschichte' (Berlin 1902; 20th ed., 1912). Other works are 'Kreuzungen' (novel; Berlin 1904); 'Hochzeit' (drama; Berlin 1908); 'Hans und Grete,' (short stories; Berlin 1909); 'Der nackte Mann' an historical novel (Berlin 1912). A translation of his short story, 'Mara,' is given in 'German Classics' (Vol. XIX, New York 1914).

STRAUSS, Johann, Austrian composer of dance music: b. Vienna, 14 March 1804; d. there, 25 Sept. 1849. He was violinist and assistant conductor in Lanner's orchestra; and in 1824 organized an orchestra of his own, with which he made a number of tours, going to England in 1838. In 1845 he was appointed to conduct the court balls at Vienna. His musical compositions, mostly waltzes, number about 250. They raised the standard of dance music to a high artistic level. Among the waltzes are 'Lorelei'; 'Gabrielen'; 'Victoria'; 'Bajaderen'; 'Taghioni'; 'Kettenbrücken', and 'Donau Lieder.' Consult Lange, F. J., 'Lanner and Johann Strauss' (Vienna 1914).

STRAUSS, Johann, German composer, son of the preceding: b. Vienna, 25 Oct. 1825; d. there, 3 June 1899. Though his father strongly opposed his musical aspirations he became conductor of an orchestra in a popular restaurant, after the death of his father uniting the latter's and his own orchestras. He conducted the summer concerts in Petropauloski Park in Saint Petersburg 1855-66, and the court balls 1863-70 and made tours throughout Europe. 'The Beautiful Blue Danube' is the most celebrated of more than 500 waltzes composed by him, of which many others gained great popularity. He also composed successful operettas, including 'The Carnival in Rome' (1871); 'Indigo' (1871); 'Die Fledermaus' (1874); 'Cagliostro' (1875); 'Prinz Methusalem' (1877); 'Das Spitzentuch der Königen' (1880); 'Der lustige Krieg' (1881); 'Eine Nacht in Venedig' (1883); 'Der Zigeunerbaron' (1885); 'Simplicius' (1887); 'Ritter Pasman' (1892); 'Fürstin Ninetta' (1893); 'Jabuka oder das Apfelfest' (1894); 'Waldmeister' (1895); 'Die Götten der Vernunft' (1897); 'Aschenbrodel' (ballet, 1897). Consult Eisenberg, L., 'Johann Strauss' (Leipzig 1912); Prochazka, R. Von, 'Johann Strauss' (Berlin 1900).

STRAUSS, Joseph, American naval officer and inventor: b. Mount Morris, N. Y., 16 Nov. 1861. He was graduated from the United States Naval Academy in 1885, and was engaged in hydrographic surveys on the east and west coasts of the United States and in Alaska 1887-90. He spent three years in the bureau of ordnance, Navy Department in 1893-96, and here invented the superposed turret system of mounting guns on battleships. He was then in charge of the United States Naval Proving Ground at Indian Head 1900-03. The powder factory was completed during the first year of

this service and its operation begun. His next cruise was as navigator and executive officer on the monitor *Arkansas*. He was again ordered to the proving ground for two years as inspector in charge; was next executive officer on the *Montana* during a period of one year, after which he was in command of the *Montgomery*, conducting experiments with torpedoes. In 1910-12 he was assistant aid for material, Navy Department. He was a member of the commission to determine the cause of the sinking of the *Maine*. October 1912 he was ordered to command the battleship *Ohio*; October 1913, he became chief of the bureau of ordnance, Navy Department. He was promoted rear-admiral in 1918.

STRAUSS, Richard, German musician and composer: b. Munich, 11 June 1864. He studied music at Munich, was made court musical director there in 1886, and became court kapellmeister successively at Weimar (1889), Munich (1895) and Berlin (1898), with the Royal Opera. He has made extensive concert tours of Europe and he visited the United States in 1904. Strauss is one of the most successful song writers and composers of music therefor in the German language. He is one of the great masters of orchestration; and he has done much to improve program music. Much of his work is weak in invention but his wonderful technical skill is always in evidence. In addition to songs and chamber-music, he published a symphony (1884); a fantasy for orchestra, 'Aus Italien' (1886); the "symphonic poems" 'Don Juan' (1889); 'Tod und Verklärung' (1890); 'Macbeth' (1891); 'Till Eulenspiegels Lustige Streiche' (1894); 'Sprach Sarathustra' (1896); 'Don Quixote' (1898); 'Ein Heldenleben' (1899); 'Sinfonia Domestica' (1904); 'Salome' (1905); 'Elektra' (1909); 'Der Rosen Kavalier' (1911); 'Ariadne auf Naxos' (1912); 'Joseflegende' (1914); 'Alpen-Symphonie' (1915); 'Festliches Praeludium' (for orchestra); 'Enoch Arden'; 'Das Schloss Am Meer'; 'Taillefer'; 'Deutsche Motette'; 'Bardengesang.' Consult Bie, O., 'Die moderne Musik und Richard Strauss' (Berlin 1906); Henderson, W. J., 'Modern Musical Drift' (New York 1904); Huneker, J. G., 'Mezzotints in Modern Music' (1899); 'Overtures' (New York 1904); Newman, E., 'Richard Strauss' (London 1908); Schmitz, E., 'R. Strauss als Musick-dramatiker' (Munich 1907); Steinitzer, M., 'Richard Strauss' (Berlin 1914); Symons, Arthur, 'Studies in Seven Arts' (New York 1906); Urban, E., 'Richard Strauss' (Berlin 1901); 'Strauss contra Wagner' (Berlin 1902); Weingartner, Felix, 'Post-Beethoven Symphonists' (New York 1906).

STRAW MANUFACTURE. The use of straw in manufacture is varied and extensive. Besides its use in the making of paper it is woven into hats, baskets, bottle covers and saddles. Straw hats were first made and worn by the Romans, but the industry did not receive any impetus until about the 16th century, when Mary, Queen of Scots, engaged a number of straw-plaiters of Lorraine to return with her to Scotland to instruct her people in their art. The principal sources from which the United States imports straw are Italy, China, England, Switzerland, Japan, Belgium and France. It is estimated that in Saxony and Bohemia there

are from 20,000 to 30,000 persons engaged in straw manufacture. The finest straws and braids are imported from Tuscany, where a fine grade of straw is produced, from which the delicate Leghorn braid is made. Some of the braids are so fine, and the work so trying on the eyes and nerves, that a person cannot work steadily at it more than an hour or two at a time. The Panama hat, though often classed as straw, is in reality made from young leaves of a certain kind of pine (*Coriudovica palmata*). Straw has become one of the most important materials employed in the making of cardboard and coarse paper. Straw is sometimes used with other materials in the making of better grades of paper. Straw boards are the cheapest paper board on the market. Of these about 200,000 are manufactured annually. See PAPER.

STRAWBERRY, a perennial herb of the genus *Fragaria* (order *Rosaceæ*). The species are natives of the north temperate zone and of the Andes region of South America. They are exceedingly variable, botanists having described about 130 species, which are considered only forms of about 12 species; and even these are reduced by Bentham and Hooker to only four or perhaps three. The number of hybrids—crosses and varieties—is enormous and actively changing annually, as new varieties are introduced into cultivation and inferior ones are discarded. In the United States alone there are probably 1,000 varieties offered for sale each year, and half that number are occasionally tested in a single season at some of the experiment stations. The cultivated strawberries are derived from four species which are characterized by palmate, trifoliate leaves produced upon very short stems often less than an inch long and usually called a crown. The white or yellow, perfect or pistillate, flowers are borne in corymb-like racemes upon scapes which arise from the axils of the leaves. The pistils develop into small hard akenes, "seeds," persistent upon the enlarged pulpy, edible receptacle, the "berry," which in some varieties is white, but in the majority red. In Europe the hautbois strawberry (*F. moschata*) is somewhat cultivated for its dull red berries which are noted for their musky odor. They are seldom grown in America. Another European species, *F. vesca*, the alpine or perpetual strawberry, is also cultivated abroad, where its high quality and continuous bearing have rendered it popular in private gardens for which places it should be, but is not, very popular in America. The scarlet or Virginian strawberry (*F. virginiana*) is a native of eastern North America, where it is the common wild strawberry. It has been cultivated to some extent, but is more or less blended with other species, especially the following. The Chilean strawberry (*F. chilensis*) is a native of the Pacific Coast of South America, with large, dark red, firm, fragrant fruits, which through its botanical variety, *F. chilenses*, var. *ananassa*, the pine or common garden strawberry, is the parent of the vast majority of horticultural varieties cultivated in America if not throughout the world. This species was introduced into cultivation early in the 18th century.

The first successful American variety, the Hovey seedling, was introduced in 1834 or 1835, up to which time the European varieties had

been cultivated in gardens. But not until 1854, when the Wilson or Wilson's Albany was introduced, can strawberry growing be said to have gained a footing upon a commercial scale. This firm-fleshed, large-berried variety quickly proved itself adaptable to a great variety of soils throughout the whole country, and its wonderful productivity led to its extensive planting. The growth of the industry has been so rapid and has reached such proportions that one writer asserts that probably more strawberries are shipped into New York in a day during the busy season than appeared in its markets during its history up to 1840. Commencing in Florida and the Mississippi Delta during February or earlier the strawberry "season" travels northward to Canada where it closes in July. And during this "season," which lasts usually from two to three weeks in a locality, there are often trainloads of berries sent to market each day. In some of the more important regions such as the coastal plain of North Carolina, the Chesapeake Peninsula and western New York, the rate often reaches a carload a day for each mile of railroad through the shipping district. The berries are mostly used as dessert, but immense quantities are used for canning and for making jams and jellies. Various beverages and fruit syrups are also made from them.

Strawberries are propagated by means of seeds, division of the crown and by runners. New varieties are almost invariably grown from seeds, no two of which from the same fruit can be reasonably expected to produce plants identical as to vigor, productivity, season of maturity, etc., and among which if taken from ordinarily good fruits the proportion of valuable new varieties is probably less than one in 10,000. With seeds produced by hand-pollination of individual blossoms, and under the most careful management, the proportion may be one in 1,000 seedlings. All or almost all of the improved varieties have been produced in this way, only a very few being obtained by selection of individual plants, though this method is really operative more or less unconsciously in all plantations. Division of the crown is very rarely practised with American varieties but is more common with European. It consists in cutting the old plants apart so as to have roots with each part; after management is about the same as for runners. Very few of the strawberry plants grown in America are grown by other methods than by runners, which are produced freely by most varieties and will become independent plants usually within three or four weeks if covered with earth. When rooted they may be dug, trimmed and planted, care being taken to place the crown level with the surface of the ground. Sometimes they are rooted in pots for planting in autumn. In such cases they may be allowed to fruit the following season, and are usually allowed to bear two crops before being turned under, since they are more costly, and since the ground is generally cleaner by this method of management than by the common one. Sometimes the runners are dug in the spring, planted closely in nursery beds for a month, during which the soil is thoroughly worked to get rid of weeds and make it fine, and the plants which have developed numerous roots set preferably just before a shower.

Strawberries will succeed well upon almost any soil except the sandiest and the undrained mucky soils. They thrive best, however, upon rich sandy loam well drained but moist rather than dry. These may be anywhere in the United States or Canada where corn will mature and even in some places where the season is too short or the nights too cold for that. They should not be planted upon low ground, since in such places the blossoms are frequently destroyed by late spring frost unless expensive precautionary measures are taken. High land from which the cold air will readily descend, and upon which the flowers may open somewhat later, especially if the exposure be to the north, should be given the preference. If the soil has been in sod for several years it should be planted to corn or potatoes for at least two years to permit the ground to be brought into perfect condition and to allow the larvæ of various root-feeding insects a chance to escape, otherwise they, being deprived of their natural food, may injure the strawberry plants. During these two years liberal applications of stable manure should be given and the ground made as free from weeds as possible by thorough cultivation. If a crop of early potatoes be grown they may usually be harvested in time to allow autumn planting and except for harrowing, the land may not need further preparation. Usually, however, spring planting is preferred, the ground being plowed as deeply as practicable without turning up the subsoil. It is then harrowed and marked off in rows about 30 inches apart and the plants set by hand or, upon a large scale, by transplanting machines. During the first season most growers destroy the blossoms because it is considered that fruit bearing this season stunts the growth and impairs fruitfulness during the succeeding year. Since the plants are low growing and unable to fight weeds and also produce well clean cultivation is essential throughout the growing period. After the fruiting season runners will appear (often they come earlier) and should be allowed to root so as to form a more or less continuous row which by the end of the autumn should be about 18 inches wide. Some growers who supply fancy markets or special customers grow the plants in "hills" or "stools," the runners being destroyed and the original plant encouraged to develop additional crowns. As soon as the ground freezes a mulch of marsh hay, straw, pine needles or other material free from weed seeds, is spread liberally upon the plants to keep the frost in the soil and prevent heaving of the plants and the consequent breakage of the roots. In the spring this mulch is either removed entirely from the field or is raked between the rows. In the former case one or two cultivations are usually given; in the latter, none. Either at this time or during the previous summer, or at both times, applications of commercial fertilizers may be made, the kinds and amounts depending upon the grower's idea of the needs of the plants and the richness of the soil. Wood ashes, muriate or sulphate of potash, dried blood, ground bone and superphosphates are favorite fertilizers. Nitrate of soda and sulphate of ammonia must be given with caution since they may tend to an abundant growth of foliage at the expense of fruitfulness. If, however, the leaves

are yellowish, one of these should be given as a rule. When the berries have become fully colored they are gathered with the stems on and shipped to market in crates containing 24, 32 or 36 quart boxes. A yield of 200 bushels per acre is not uncommon and more than double that is often obtained by the most careful growers in favorable years. As soon as the crop has been gathered the plants are plowed under and the land planted to such crops as cabbage, turnips, beets or other plants that require only a short season to reach maturity. Sometimes if the land is exceptionally clean, when the crop has been light, or where the plants are especially vigorous, they may be allowed to remain for two seasons; the second crop, however, is usually lighter than the first and the beds are likely to become weedy even under best management. A favorite rotation is corn, potatoes, strawberries, cabbage, and grass and clover used for hay one or two years or pastured for several.

Strawberries are occasionally forced in greenhouses to supply a small demand among the wealthy. The plants are usually grown in pots because they can be better controlled than in benches and because they may be sold for decorative purposes as well as for dessert. They are generally potted in early spring and the first runners from them rooted in small pots which when full of roots are discarded for large pots in which these plants are to bear fruit. The pots are then kept in deep beds of ashes, preferably under a cold frame in which great care is directed to watering, especially toward and during autumn when it is gradually withheld, the plants even being allowed almost to wilt, in order to shorten up their growth and to store reserve food. After freezing, the plants may be removed as desired to the greenhouse, at first to low temperatures and later to higher ones in imitation of spring. In about eight weeks the fruit should be ready, but all through great care must be exercised in management, especially as to humidity of the air, ventilation, and pollination of the flowers, an operation that must be done by hand with a camel's hair brush, preferably.

Under the best management strawberries are seldom seriously injured by insects, although a considerable number are partial to this plant. The larvæ of several root-feeding beetles are sometimes troublesome, if the grower plants his strawberries upon a freshly turned sod. But this may be obviated by two or perhaps even one intervening crop of potatoes or corn. There are also several beetles which enjoy the blossoms, tender foliage or fruits, but since these travel slowly they may be avoided by selecting new ground each year. There are a few general feeding insects such as caterpillars, plant bugs, etc., which occasionally vary their diet with strawberries, but they are rarely troublesome. Several so-called plant diseases have been reported as causing losses in plantations, but very frequently the cause may be readily traced to other sources, such as planting in unsuitable soil, or upon lowlying land, by insufficient vigor of plant, due to lack of plant food, etc., but especially to continued use of the land for this one crop. All the above may be avoided by proper rotation, the strawberry being allowed to occupy the land

only one year or in exceptional cases two years, and the ground being thoroughly cleaned by cultivation and judicious rotation before strawberries are again planted upon it.

Y., 1891); Terry and Roet, 'How to Grow Strawberries' (Medina, Ohio, 1890); Fuller, 'Strawberry Culturist' (New York 1862, and later editions); Pardee, 'Manual of the Cultivation of the Strawberry' (New York 1854, and later editions); and numerous bulletins of the Agricultural Experiment Stations.

STRAWBERRY BASS, one of the many local names in the Mississippi Valley of a large and handsome sun-fish (*Pomoxis sparoides*), closely related to and resembling the crappie, but having the mottlings a clearer green and tending more to become spottings. It reaches a length of 12 inches, is a favorite game fish for young anglers, is good food and is abundant in clear cold streams and ponds. Other names are calico bass, grass bass and bar-fish.

STRAWBERRY BUSH. See SPINDLE TREE.

STRAWBERRY SHRUB, a shrub (*Calycanthus floridus*) native to the southern United States, which is widely cultivated for its flowers. These are dark purple, terminating leafy branches, with many series of imbricated strap-like sepals and petals. When crushed they give out a delicious aromatic fragrance which has been likened to that of strawberries or of fermenting wine. The receptacles are hollow and enclose the pistils; at maturity the receptacles enlarge (the bases of sepals, petals and bracts still adhering) into an urn-shaped capsule holding the true fruits or achenes. The leaves are ovate, rough above and pubescent beneath, and, together with the twigs, have an odor of cloves. Western species of the genus have like aromatic foliage and flowers, but *C. fertilis* bears inodorous blossoms.

STRAWBOARD, the name of a very thick, coarse cardboard, made of straw after it has been boiled in lime and soda to soften its texture. It is one of the products of paper mills and is manufactured by machinery similar to that used in such mills. The cheaper grades of strawboard are largely utilized in making boxes. The finer qualities are utilized in making book covers.

STREAK, in mineralogy, is the essential color of a mineral, or the color of its powder. It is most commonly obtained by rubbing the specimen on a tablet of rough white porcelain or on a piece of white hornstone. Any method may be employed which makes it possible to see the powdered mineral. It is a property of first importance in all schemes for the determination of minerals by their physical properties and is of especial value in differentiating the metallic minerals, whose external colors are often identical while their streaks may be very different. The greenish-black streak of chalcopyrite instantly distinguishes it from gold whose streak is like its external color. The red or reddish-brown streak of hematite serves to identify it when compared with the ochre-yellow or rust-

brown streak of limonite, or the black of magnetite.

STREAM LINES. In the flow of fluids (including gases and liquids), the path described by any infinitesimal portion, or particle, of the fluid is called a stream line. The theory of stream lines is a part of the mathematical science of hydrokinetics. The most important result of this theory is known as the principle of Bernoulli (Daniel). It asserts that in the steady motion of liquids (or fluids of constant density) the sum of the pressure, the kinetic energy per unit volume and the potential energy per unit volume of the liquid, is constant along a stream line. The principle holds also, with a slight modification of statement, for the case of gases. This principle accounts for the fact that in the steady flow of liquids through tubes of variable cross section the pressure is least where the velocity of the liquid is greatest and vice versa, supposing the potential energy per unit volume of the liquid unchanged. It explains also the action of the Venturi water meter, the aspirator, the ball-nozzle contrivance and other mechanical devices. Consult Appel, 'Traité de Mécanique Rationnelle'; Lamb, 'Hydrodynamics.'

STREAM PIRACY. Streams which are favorably located can cut down their channels and extend their tributaries faster than less favored streams. This is particularly true of those that are located in areas of softer rocks where less energy is required to erode. Such streams often extend their headwaters so rapidly that they encroach upon the less favorably located rivers and capture portions of their drainage. The former stream is said to behead the latter and the process is called stream piracy. In the Appalachian region, where many of the larger streams occupy parallel valleys on softer rocks, those streams which flow across the harder rocks are often beheaded by the larger rivers on the softer beds. The old valley notch across the hard ridge, which constituted a water gap, becomes abandoned and is then called a wind gap. See TRELLISED DRAINAGE.

STREAM TIN, the name applied to cassiterite when it occurs in the form of sand or small pebbles in the beds of streams or in adjacent bottom lands. Owing to the great hardness, density and insolubility of cassiterite, it is readily concentrated by running water, and accumulates in extensive deposits, thus constituting an important source of supply of tin ore. It is largely worked in Australia, Tasmania, the East Indies, and formerly in Cornwall, England. See CASSITERITE.

STREATOR, Ill., the largest city in La Salle County, on the Vermilion River, and on the Atchison, Topeka and Santa Fe, the Chicago, Burlington and Quincy, the Chicago and Alton, the Wabash, the New York Central, the Chicago, Ottawa and Peoria railroads, 90 miles southwest of Chicago. The city was developed as a coal-mining centre, mining commencing about 1868. The city was incorporated in 1882. It lies in the fertile agricultural region known as the northern Illinois corn belt, and is underlaid with coal and shale. The manufacturing establishments include glass and bottle factories, brick, drain tile and sewer pipe works,

automobile factories, automobile accessory works, agricultural implements, washing machines, windmills, acetylene plants, foundries, detinning factory, etc. The latest census of manufactures reported 60 manufacturing establishments employing 1,918 persons, of whom 1,770 were wage-earners. The capital invested in these establishments was \$6,993,000, annual amount of salaries, \$150,000; wages, \$1,045,000; the cost of materials, \$1,762,000, and the value of products, \$3,887,000. The trade is chiefly in manufacturing, coal, grain, livestock and dairy products. The principal buildings are the Federal building, municipal buildings, opera houses, hotels, Y. M. C. A. building, City Club, Elks' building, Masonic Temple, public library, Saint Mary's Hospital and about 25 large well-equipped churches. The educational institutions are a large high school, well-equipped public schools, parish schools, a kindergarten, private commercial schools, library and Y. M. C. A. reading rooms. The three national banks have a combined capital of \$300,000. There are four thriving building and loan associations, and a large number of fraternal societies, lodges and organizations. Pop. 16,500.

STREET, Alfred Billings, American nature poet: b. Poughkeepsie, N. Y., 18 Dec. 1811; d. Albany, N. Y., 2 June 1881. From 1848 until his death he was State librarian of New York. Though diffuse, his verse displays a love of nature founded upon close and accurate observation and scarcely deserved the neglect into which it has fallen. His published works include 'The Burning of Schenectady and Other Poems' (1842); 'Drawings and Tintings' (1844); 'Fugitive Poems' (1846); 'Frontenac' (1849); 'Woods and Waters' a volume of Adirondack travel (1860); 'Forest Pictures in the Adirondacks,' poems (1865); 'The Indian Pass' (1869); 'Lake and Mountain' (1870); 'Eagle Pine' (1871).

STREET, George Edmund, English architect: b. Essex, 20 June 1824; d. 18 Dec. 1881. He was educated in Mitcham and Camberwell and received part of his professional training under Sir G. G. Scott, and like him held the Gothic style in highest favor, the numerous lectures and papers which he wrote on architecture being all directed to illustrate the history and principles, and promote the progress of that style. His principal literary works are 'The Brick and Marble Architecture of North Italy in the Middle Ages' (1885); and 'Some Account of Gothic Architecture in Spain' (1865). He was for many years engaged in the work of erecting and restoring churches and other ecclesiastical buildings. In this connection he designed Cuddesden Theological College, the Crimean Memorial Church at Constantinople. Saint Paul's (American) Church at Rome, the Law-Courts at London and various other churches in Oxford, Liverpool and other parts of England. He was also one of the most successful of church restorers, among his restorations being the cathedrals at York, Bristol and Carlisle and various noted chapels. In 1868 he was appointed architect of the new Courts of Justice in the Strand, London, after a competition in which were engaged the most famous architects of the day. This gigantic undertaking was not quite completed at his death. In 1866 he was elected an Associate of the Royal Acad-

emy and in 1871 became a Royal Academician. In the last year of his life he was appointed professor of architecture at the Royal Academy. Among his published works are 'The Brick and Marble Architecture of Northern Italy in the Middle Ages' (1885); 'Gothic Architecture in Spain' (1865). Consult a memoir by his son, A. E. Street (1888).

STREET, Julian Leonard, American author: b. Chicago, 12 April 1879. He was educated at the public schools and Ridley Preparatory School, Saint Catharines, Ontario. He started as reporter for the *New York Mail and Express* (1899) and had charge of the dramatic department 1900-01. He has written 'My Enemy the Motor' (1908); 'The Need of Change' (1909); 'Paris à la Carte' (1911); 'Ship-Bored' (1911); 'The Goldfish' (1912); 'Welcome to our City' (1913); 'Abroad at Home' (1914); 'The Most Interesting American' (1915); 'American Adventures' (1917).

STREET (Latin *strata*, Anglo-Saxon *stræt*, road) an open way or thoroughfare within the corporate limits of a city or town. In the rural districts streets are called roads or highways. Very primitive cities seem to have been built without real streets, much after the manner of Indian villages; but as population and the activities of communities grew, the necessity for better means of communication within the towns themselves and between them and the surrounding country arose and called into being the more regular distribution of buildings. In the large cities of pre-Columbian America, with a few notable exceptions, the buildings seem to have been grouped irregularly around a public square, along the four sides of which were paved roads. From this square, at first, exit was had by one or two highways along which were grouped buildings of many kinds. This seems to have been the only evidence of the regular placing of buildings in a town. This constructive plan, or rather lack of plan, is strongly in evidence in the ruins of the cities of the early period of semi-modern civilization in Yucatan. In the ruined city of Uxmal (q.v.) the central plaza is occupied by a great flat-top pyramid, terraced in form, round which are grouped the other important buildings on high pyramids or elevated terraces but without any evidence of plan. But in some of the later cities the pyramid is found surrounded by an open space consisting of the outer edges of the central plaza. From this plaza, roads led in various directions, often for hundreds of miles into the country. These were efficiently paved and maintained at the expense of the general government. From the heart of the city of Itzamal led, far into the interior, four excellently paved roads over which the traffic was immense. Each of these roads started from one of the four corners of the central plaza, the broad ground-level space of which was handsomely paved with carefully-cut large stone blocks. From the ancient Chiapan city of Palenque stretched a well-paved street for over a hundred miles into Guatemala. All along this street, intermittently, were stone buildings, the ruins of which are still in evidence. This was evidently a great highway of commerce and general traffic, especially to the sacred shrines of the city. These great highways seem to have preceded the organization of cities and towns

into sections divided by more or less geometrical streets. Most primitive towns are very irregular in their structure and the more primitive they are the more a matter of accident seem to be the arrangement, the width and the construction of the streets, which are generally (when they do exist) narrow, crooked and irregularly placed. Excavations of ruins where one city has been built upon the remains of another show, often, that the older town was much more irregular in its street structure than the later.

As nations began to extend their commerce, trade and other relations, they generally improved their roads and streets. The construction of the magnificent streets of the cities of the Roman Empire seems to have been along the same line of growth as that of the later civilized empires of America. Two necessities compelled the building of magnificent highways—commercial activity and political requirements. No one other factor gave more efficiency to the Roman Empire than its system of magnificent roads. These, in their turn, brought commerce, trade, commercial importance, wealth and luxury to the greater cities. All these called for more sanitary modes of living and better facilities for moving about the cities and towns. This brought into being a more geometrical organization in many cities and towns and the construction of magnificent well-paved streets and avenues, many of which were lined with stone benches and handsome statues. The famous "Appian Way," known as the "queen of roads," stretched away from the heart of the Rome of the empire for a distance of 350 miles, every mile of which displayed some feature worthy of attention. It was quite natural that such great roads, lined with magnificent palaces and other noteworthy edifices, should have had their effect upon the streets of the cities of the empire.

But after the fall of Rome the art of city street construction declined throughout Europe. Under Germanic and Gothic influence new cities and towns were constructed with narrow, crooked, unsanitary streets, many of them little better than alley-ways, in which plagues, fevers and other diseases made their homes. When the streets were paved at all it was generally with loose cobble-stones and later with roughly cut stones in the more progressive cities. The old Roman art of building cement ways seems to have been completely lost, forgotten or neglected. Here again the old story has repeated itself. The rapid extension of trade and commerce during the 19th century, the invention of the steam engine, the locomotive and the steam-boat called for the extension of highways and the material improvement of those already existing. These, in turn, brought increased population and wealth and importance to the cities and towns. In their train came the improvement of the city streets. The invention of the bicycle and the automobile led, about the beginning of the present century, to the rapid extension of the city boundaries and the introduction of wide avenues and streets in the modern city planning and construction. These factors have brought with them many improvements in street pavement. The ancient cobble-stones were replaced by carefully-filled rectangular wooden blocks, cut stone and brick. These are being rapidly replaced by the more

durable and sanitary asphalt and cement pavements. Handsome sidewalks are taking the place of the old-fashioned narrow walks of a generation ago. Even in the United States the board walks are disappearing as the price of lumber continues to advance.

The tendency now is more and more to turn over the management of city streets to experts in city planning and beautifying, and it is safe to say that the future city and town street is destined to be as great an improvement on the present street as the present is on that of the past century. The planning of the streets of a city, their connection with proper recreation parks, their pavement, drainage, lighting, water supply, gas conductors, telegraph and telephone lines, street railways, policing, flushing and cleaning, all now form proper subjects of municipal forethought and regulation. The days when the fates took care of the health of a city are past. The health officer has come into his own; and to the attention given by him to the city street is due the banishment of the most fearful of the ancient scourges of great centres of population, making the cities more healthful than the rural districts. (See CITY; MUNICIPAL GOVERNMENT; CITY PLANNING; ROADS AND HIGHWAYS; PAVEMENTS; DRAINAGE; ELECTRIC LIGHTING; RAILWAYS, STREET). Consult Doolittle, F. W., 'Urban Transportation Service' (New York 1916); Holt, R. B., 'Tramway Track Construction' (New York 1915); Robinson, C. M., 'The Wealth and Arrangement of Streets' (New York 1911); 'City Planning' (1916); Walker, E. K., 'City Planning' (*Civic Bulletin*, Berkeley 1914).

STREET CLEANING, a term used to include all operations of municipal departments charged with keeping the streets free from litter which might affect the public health or comfort, or offend the public taste. In the larger cities of the world the work consists of the daily sweeping of all paved streets; the collection of house refuse—garbage, ashes and light waste—when deposited by the householder in cans on the sidewalk or adjacent thereto; the removal of dead animals from the street; summer sprinkling to lay the dust; and the disposal of snow in winter. In small communities the term covers only the more pressing of these functions—the removal of dead animals and household garbage and ashes, with a spring cleaning of the streets after the melting of winter snows, and an autumn cleaning after the fall of the leaves.

The routine work of street sweeping and the removal of household waste is performed by men regularly employed by the department; while work which varies much with the season, such as the removal of dead animals, street sprinkling and the disposal of snow, is, in most cities, let to contractors who are subject to the call of the department, but are better able to supply the sudden demands for men and teams at any point.

For a long time in Europe, and of late in America, the men of the departments of street cleaning have been protected in their employment by civil service rules which insure their positions during efficiency and good conduct; and in Europe they receive pay during sickness and pensions on retirement. This has had the effect of providing a class of men suited to

the work and contented with their positions, and in raising the morale of the departments. In Europe the men sometimes wear distinctive caps or some other badge of employment, and in some cities they wear a modest uniform. In New York City the sweepers are garbed in white, because this is most conspicuous on a crowded street and conduces most to the safety of the men and the efficiency of the department; and because these uniforms, to be kept white, must be thoroughly washed and always in good sanitary condition. In many of the older and larger cities of Europe—Vienna, for example—where strict obedience to law has long been rigidly enforced, each householder keeps his portion of the sidewalk uniformly and always clean, having it sprinkled and swept twice daily in summer and kept clean in winter; while in New York few householders regard it as a duty and a point of honor to keep their individual sidewalks clean in summer and free from snow and ice in winter. In New York it is very common to see a newspaper dropped on the street with no protest, whereas in Europe such an act would almost certainly cause a man's arrest if he refused to pick up the paper. There are streets in New York where one sweeper keeps clean 20,000 square yards of pavement; there are other streets, in the crowded districts, where one man's work is to keep clean 1,000 square yards. In the latter case the pavement is laboriously swept seven times daily.

The late Street Commissioner Waring, of New York, at the close of his administration made a report considering in succession 13 factors which were deemed to be beyond the control of the department, and for each was determined approximately its relative difficulty. They were:

- (1) Kind of pavement — asphalt, 100; wood, 100, brick, 100; granite, 150; Belgian block, 160; cobble, 400.
- (2) Condition of pavement — good, 100; fair, 120; bad, 140.
- (3) Amount of traffic — light, 100; medium, 140; heavy, 180; dense, 250.
- (4) Amount of car track — on basis of 30-foot street with single track.
- (5) Kind of car track rail — none, 100; flat or grooved, 110; T rail, 120.
- (6) Amount of sanding — little, 110; much, 120.
- (7) Amount of sprinkling — heavy, 125.
- (8) Elevated railroad — 110.
- (9) Character of population — good, 100; fair, 200; bad, 300.
- (10) Presence of schools — 110.
- (11) Existence of markets — 125; or (12) Push-cart stands — 175.
- (13) Vicinity of unpaved streets — 200.

That a street bears heavy traffic is seen to have more influence on the labor of sweeping than that it has granite instead of asphalt pavement. The amount of traffic affects the cost; but no other single cause contributes so much to the difficulty and expense of sweeping as the action of careless and thoughtless persons in making the public streets the receptacle of all kinds of rubbish—fruit parings, bits of paper, etc.—of which they wish to be rid, and which a little consideration would induce them to deposit in some can which might be emptied into a cart without the trouble of sweeping and shoveling from the pavement.

Machine sweepers (horse or automobile) lessen the cost of street cleaning, and may be used to advantage with preliminary sprinkling

on wide, level, well-paved streets, between midnight and dawn; but their service on crowded streets in daytime is impracticable.

A fall of snow is such an impediment to city traffic, which is usually conducted on wheels even in winter, that it is recognized as a duty of the departments of street cleaning to remove it promptly from important streets, especially from the lines of daily food distribution and from the avenues of daily approach to the business districts. The numbers of men and teams suddenly required are very large, and dumping facilities are in general quite inadequate to the work. The cost is also great—about \$125 per mile of street per inch of snow, or \$1,250 per mile of street for a 10-inch fall. For these reasons numerous efforts have been made to develop practical processes for melting the snow as it lies, or at least on the block where it lies, and running the water into the nearest sewer opening. Machines for the purpose have been tried in many cities for many years, but have usually proved unequal to the task, because of the cost of melting. The most satisfactory method where there is plenty of water in the city pipes, that is well above the freezing point, is to turn a hydrant hose on the snow and wash it down the gutters. Of course this method is applicable only to a light fall, or to the remnant of a heavy snow-fall.

In all street dirt disease germs lurk in unknown numbers, and when the dirt is dry and dust is raised by passing traffic or by winds, the dust and the germs find lodgment in eyes, nostrils and mouths, and the work of disease is begun. Of course the dust and the germs are the thicker the nearer the pavement, and no other cause is necessary to explain why the children of the crowded streets are so affected. Careful experiments carried out in New York by Commissioner Woodbury, with germ cultures from plates exposed, some at the curb level and some at six feet above, exhibited a wonderful difference in the number of germs which found lodgment on the plates in different parts of the city. At the curb level the evidence of the plates showed on the average five times as many germs as at six feet above. In a tenement district densely populated, where push carts are numerous and traffic heavy, as many as 9,600 germs were caught in a 15-minute exposure of a plate two and one-fourth inches in diameter. In another part of the city, in a residential district, with heavy traffic but well-flushed pavement, only 54 colonies were found after a 15-minute exposure.

The relative costs of street cleaning in different cities of the world are impossible of comparison, because the conditions and the standards of cleanliness vary so much, and because the work of the department has nowhere been reduced to an exact science. But in general the cost in Europe is much less than in America because of the greater waste and carelessness of the average American citizen, and because of the lower wage cost in Europe. The cost of street cleaning in Manhattan and the Bronx, including the collection and removal of house waste but not the removal of snow, before the war prices set in was about \$7,000 annually per mile of street. In Vienna, where only some 25 miles of street in the heart of the

city is kept thoroughly clean, the annual cost, excluding snow removal, was about \$5,000 per mile. In Budapest, where the pavement is excellent and where much value is recovered by sorting the wastes, the annual cost was not far from \$2,000 per mile. In Paris it was about the same. In Brussels the cost was about \$1,350 per mile. In Birmingham, England, the cost was still less, though wages were higher than on the Continent. See WASTES, CITY, DISPOSAL OF.

STREET RAILWAYS. See AMERICAN STREET RAILWAYS; RAILWAYS, STREET.

STREIGHT'S RAID FROM TUSCUMBIA, Ala. In the spring of 1863 General Rosecrans organized an expedition to cut the communications of General Bragg's army, then at Tullahoma, Tenn. The objective point was the railroad south of Dalton in northwestern Georgia. For this purpose Col. A. D. Streight, 51st Indiana, who had suggested the expedition, was designated to lead it, and was given a provisional infantry brigade of 1,700 men, composed of the 51st and 73d Indiana, 80th Illinois, Third Ohio and two companies of Tennessee cavalry. He was ordered to Nashville to organize the expedition. His instructions were to descend the Cumberland River to Palmyra, thence to Fort Henry, on the Tennessee, and sweep around the rear of Bragg's army, cut all his railroad communications in northern Georgia, destroying manufactories and depots of supplies, and in every way to cripple the Confederates. Having obtained a partial outfit of unserviceable mules, depending upon the country for a further supply, Streight left Nashville 11 April, with his troops on steamboats, and landed at Palmyra, from which point he marched across to Fort Henry, gathering on the way as many serviceable mules as possible. He remained at Fort Henry until the fleet of steamboats went down the Ohio and up the Tennessee to that point, when he again embarked his men on the 17th and landed at Eastport on the 20th of April. On the 21st, with General Dodge, who with 7,000 cavalry and infantry had marched by way of Corinth and luka, to protect the movement, he moved on Tuscumbia to mask his real intention. Following Dodge, who steadily pushed back Roddey's cavalry, he arrived at Tuscumbia on the 24th, and being supplied by Dodge with some animals and rations, and leaving his sick and disabled men with Dodge, who was to return to Corinth, after holding the enemy until Streight could get a good start, at midnight of 26 April, with only 300 of his 1,500 men on foot, Streight cut loose from Dodge, started southward in a heavy storm, and scouring the country for horses and mules arrived at Moulton, after some slight skirmishing, about dark of the 28th. At midnight, every man being mounted, he resumed the march eastward to Day's Gap, about 35 miles, bivouacking on the night of the 29th at the east foot of the gap. March was resumed before daylight next morning, and before his rear guard had cleared the gap Forrest's cavalry was upon it. With 1,200 men and eight guns Forrest had left Courtland, Ala., 16 miles north of Moulton, at the same hour Streight had left Moulton, and with scarcely a halt had overtaken him. Streight formed an ambuscade into which Forrest rode and

was repulsed with the loss of two of his guns. This check, with Forrest's necessity for rest, gave Streight an advantage of time, which he improved, and in the forenoon of 1 May he reached Blountsville, after a running fight in which he was hard pressed and some of his men captured. Here Streight seized fresh animals, discarded wornout ones, distributed ammunition and rations, burned his wagons and near noon started for Rome, Ga., the seat of extensive iron works, which he thought to destroy. His column was not fairly in motion before his rear guard was attacked in the streets of the town. There was a running fight from Blountsville to the Black Warrior River, and upon reaching the river Streight was compelled to make a stand. Forrest was beaten off, and at 5 P.M. Streight crossed the river and moved on with but little more interruption, until 9 A.M. of the 2d, when his rear guard was fiercely attacked at the crossing of Black Creek, near Gadsden. Forrest was held in check some time by the burning of the bridge and Streight continued the march to Gadsden, where he made a short halt to rest his men and animals. Continuing the march at 4 P.M., he again halted 15 miles beyond Gadsden to procure forage for his animals. Meanwhile Forrest was pressing him closely, drove in his rear guard and made a general attack, in which he was repulsed and fell back, and as it was growing dark Streight withdrew half a mile; but Forrest moving to flank him, he again resumed his retreat intending to reach Rome and burn the bridge over the Chattooga. When, near Cedar Bluffs, Ala., he was again overtaken and attacked by Forrest, he found the bridge over the Chattooga held by the enemy; his men and horses had broken down; he had no hope of accomplishing the principal object of his expedition; and at noon 3 May he surrendered 1,365 men. He had lost in killed, wounded and captured prior to the surrender 145 men. The captives were sent to Richmond and confined in Libby prison, from which Streight escaped in February 1864 by burrowing under the foundation walls. Consult 'Official Records' (Vol. XXIII); Wyeth, 'Life of Gen. N. B. Forrest.'

E. A. CARMAN.

STRELETS (pl. *Streltsi*), Russian, sharp-shooter, the life-guards of the Russian tsars until the reign of Peter the Great. They were instituted by Ivan the Terrible in the latter half of the 16th century as a national guard; for 200 years they rendered valuable service to the empire. They amounted sometimes to 40,000 highly-trained men. Their numerous privileges and their frequent insurrections made them as formidable as the Roman prætorians or the Turkish janissaries. On the death of Tsar Feodor in 1682, the double family of Alexis, his father, struggled to seize the crown. The Streltsi joined in the revolt of the people of Moscow caused by false rumors that the young tsarevitch Ivan (half-brother of Peter), had been strangled. Followed by an immense crowd, 20,000 Streltsi marched to the Kremlin, dragging cannon behind them. When the dowager tsaritsa appeared with the two princes the revolt was almost ended. A violent harangue against the rioters by Prince Mikhael Dolgoruki inflamed the Streltsi, who flung him from the top of the red staircase upon their

pikes. They sacked the palace, murdering all who fell into their hands. The violent reforms of Peter the Great met with strong opposition from the Streltsi, who likewise suffered hardships and privations while campaigning in distant and inhospitable regions. Thousands deserted from the ranks while Peter was abroad in 1697; others revolted, deposed their officers and marched against Moscow. They were stopped on the banks of the Istra by Generals Gordon and Schein with regular troops. The Streltsi presented a petition setting forth their grievances, when 4,600 were arrested. Peter hastened home from Vienna, determined to crush the turbulent troops. Hundreds of the Streltsi underwent terrible tortures; 230 were taken in carts to the Red Place in Moscow on 1 Oct. 1698, followed by their wives and children. In seven days a thousand Streltsi were executed. Peter obliged his nobles to assist at the wholesale slaughter, and it is said that on the last day the tsar himself chopped off the heads of 84 Streltsi. The removal of the corpses was forbidden; "for five months the Muscovites had before their eyes the spectacle of the dead bodies hanging from the battlements of the Kremlin and the other ramparts." The Streltsi as a distinct organization ceased to exist. Some 20,000 of the survivors were distributed among the regular army.

STRELITZIA, a genus of perennial herbs of the family *Musaceæ*. The species, of which there are less than half a dozen, are natives of South Africa, and are called bird of paradise flowers. They have stout rhizomes, more or less woody, usually short stems, long petioled, generally large paddle-like leaves, and showy flowers of striking form. The genus is closely related to *Musa* (banana, plantain, etc.), *Ravenala* (travelers' tree of Madagascar), *Maranta*, *Curcuma* and *Canna* (some of which furnish starch and arrowroot). The best-known species (*S. regina*) grows about three feet tall, and has a spathe about six inches long, purplish at its base, and surrounding the bases of about six orange and bluish-purple flowers.

STRENGTH OF MATERIALS. The relation between force and the distortion it produces in materials of construction (metal, stone, timber, etc.), the harmful effects of force, and the proportioning of materials safely to resist given forces are studied under this title. For brief notes on the history of the subject see the article **ELASTICITY**.

Stress and Strain.—Since forces are distributed over surfaces, and not concentrated at points as in the mechanics of rigid bodies, the concept of force-per-unit-area is of fundamental importance; it is called *stress* in this article although stress is generally used as being synonymous with force; this use is confusing as well as superfluous. If the stress is normal (perpendicular) to the surface on which it acts it is called normal, or tensile or compressive stress; if tangential it is called *shear*. The deformation resulting from the application of force may be manifested as a change of length, of area or cross-section, of volume, or of angle. The change of length (or area, or volume) *per unit length* (or area, or volume) is called linear (or areal, or volumetric) *strain*. Strains are purely numerical ratios; they are not lengths, areas or volumes. If a rectangle

drawn on any plane in a stressed material is distorted into a parallelogram the change, in radians, of any one of its right-angles is called the shear strain for reasons which will be evident presently. The deformation produced by stress requires time to develop. Tar, for instance, is brittle or fragile under quickly applied loads and breaks, like flint, with a smooth conchoidal fracture. It behaves like a very rigid solid under sudden blows, but under the smallest forces applied for a long time it flows as if it were a liquid; under gradually applied large forces it is plastic and can be kneaded like dough or putty. Metals behave in the same kind of way but to a decidedly smaller extent. The full effect of stress is not produced immediately although the greater part arises very quickly. If the stress is removed some of the distortion disappears at once, some takes hours, days or even months to vanish, and some remains permanently. The property of recovering from deformation is called *elasticity*. A body that recovers completely and resumes its original dimensions is said to be perfectly elastic for the particular stress that acted on it. The slow return to shape, occurring during the second period of recovery, is the elastic *after-effect* discovered by Weber in 1835; some very curious phenomena are associated with it. The after-effect has thus far been of no importance in engineering but it is not unlikely that its study will help to clear up difficulties met with in the molecular derangements resulting from stress. For an exhaustive account consult the article by Braun and Jaeger in Winkelmann's 'Handbuch der Physik,' Vol. I, 1908.

Laws of Elasticity.—For many metals and certain other materials the laws of elasticity, i.e., the relations between stress and strain, are quite simple; they date from the time of Hooke in 1678. If a tensile or compressive force F is applied at the end of a rod or bar of length l and cross-section A it produces a change of length Δl ; if the force is not too large these quantities are connected by the experimentally discovered equation

$$\frac{F}{A} = \frac{E \Delta l}{l}.$$

In terms of stress and strain, putting $F/A = p$ and $\Delta l/l = s$, we have

$$p = Es$$

where E is a constant called Young modulus; its value depends on the material and, within certain limits, not upon the stress. For iron and steel E is the same for tension as compression; for cast iron and stone this linear relation does not hold at all; for wood E depends upon whether p is along or across the grain. Typical values of E in pounds per square inch are steel (tens. or comp.) 30,000,000; cast iron (tens.) 15,000,000; concrete (comp.) 2,000,000; wood (along grain) 1,500,000.

When a bar is stretched (compressed) longitudinally its cross-section gets smaller (larger) without change of shape, all transverse dimensions in any plane growing proportionally smaller (larger). If s is the longitudinal strain and s' the lateral strain—the strain of any line in a cross-section—

$$s' = s/m$$

where m is constant for a given material and generally independent of the stress. $1/m$ is

called *Poisson's ratio* (See article ELASTICITY); for steel and iron $1/m = 0.3$ approximately.

FIG. 1.

Experiment shows that if a tangential force acts on top of a block fastened at the base, as in Fig. 1, the displacement of the top is within certain limits proportional to the force, i.e. $F \propto \Delta l$. Using q for the shear stress we may write this in the form

$$q = G \tan \phi.$$

In nearly all cases ϕ is so small as to be very closely equal to its tangent

$$\therefore q = G\phi$$

where G is the modulus of shear or modulus of rigidity; it depends on the material but in many cases not upon the stress. ϕ is the angle of shear or the shear strain; it must be measured in radians. Typical values of G in pounds per square inch are: Steel, 12,000,000; cast iron, 6,000,000; stone, 1,800,000; wood (across grain), 400,000.

All materials are compressible. If a cubical block is subjected to equal compressive stresses p on all six faces experiment shows that the volumetric strain, $\Delta v/v$, varies directly as p , i.e.

$$p = \frac{K \Delta v}{v}$$

where K is the bulk modulus and depends only on the material. As proved in the article ELASTICITY the four constants E , G , K and m are related as follows:

$$mE = 2G(1 + m) = 3K(m - 2).$$

Testing Machines.—It would seem to be comparatively simple to find experimentally the safe stress a body can carry. Yet it is not simple because it is difficult to test for one kind of stress without having some other kind present; furthermore it is not definitely known what stress or combination of stresses is the ultimate cause of failure. The precise meaning of the word "strength" is not fully understood; that is, we do not know upon what properties of a material its strength depends. The best we can do in the physical testing of materials is to find by direct and, if possible, imitative experiments the values of the elastic constants and the stresses p and q that enter the formulas derived in the rational mechanics of perfectly elastic bodies. Shear stresses are best found by experiments on circular shafts in torsion; tensile tests are made by subjecting a test piece of specified size and shape to direct pull. As both kinds of tests are made in about the same way we shall, on account of lack of space, describe only the latter. Testing machines differ in the devices used for applying and measuring the loads; they are fully discussed in Johnson, J. B., 'The Materials of Construction' (1919); Martens, Adolf, 'Handbook of Testing Materials' (translated by Henning, 1899); Unwin, 'Testing of Materials' (1910).

Testing machines may be divided broadly into three classes according to the manner in which the applied load is measured: (1) lever balance; (2) hydraulic press gage; (3) spring balance. In type (1) the load is applied by means of a screw-press or a hydraulic press but is measured with a lever balance as in the ordinary platform scales. Fig. 2 (a), after Martens, is a schematic representation of this

FIG. 2.

type; it shows only the bare principle and omits the actual arrangement of levers, supporting frame, method of gripping and applying the load, measuring the extension and details of design. The machines made by Riehle and by Olsen are of this kind; so are those made by Wicksteed in England, Martens in Germany and Marié in France, except that the lever system is attached to the upper shackle or clamp. The Olsen at the Bureau of Standards in Pittsburgh is the most powerful machine in the world, having a capacity of 10,000,000 pounds compression; it is used for tests on full-size columns and masonry piers. In type (2) one of the shackles is connected to the diaphragm of a hydraulic chamber the pressure in which is read on a gage. The load is applied at the other shackle either mechanically or hydrostatically. Fig. 2 (b) shows the essentials of an Emery machine. The Emery, designed at the Watertown arsenal in 1879 for the United States government, differs from other types in having flexible steel plate-fulcra instead of knife edges; the one at the Bureau of Standards in Washington can take specimens 35 feet long and subject them to a push of 2,300,000 pounds or a pull of half as much. The Martens machine is similar to Fig. 2(b) only the diaphragm is so arranged as to compress the water in the gage chamber; in the Whitworth a gage is attached directly to the hydraulic press that applies the load. Type (3) is represented by the Dalby weigh-bar machine. (Consult Dalby, 'An Optical Load Extension Indicator,' in Proceedings Royal Society, Vol. LXXXVI, 1912; 'Load Extension Diagrams,' ib., Vol. 88, 1913; *The Engineer* 1917; pp. 422, 453, 468). Dalby describes it thus: "The instrument is self-contained and its principal element is a hollow bar of fine steel about a foot long. This bar, called the weigh-bar, hangs by one end from the upper shackle of a vertical testing machine. The other end is coupled to the specimen bar to be broken, and the lower end of the specimen bar is secured in the lower shackle of the testing machine. . . . The cross-sections of the bars

are proportioned so that the pull applied through them is ultimately able to break the specimen bar without loading the weigh-bar beyond its elastic limit. . . . The stretch of the weigh-bar is used to determine the load,⁹ and is measured by the movement of a spot of light recorded on a photographic plate. The spot moves horizontally in proportion to the load on the weigh-bar and vertically in proportion to the stretch of the specimen bar; the resultant locus on the photographic plate is the load-stretch diagram of the specimen which is being tested. The idea used by Dalby is not new but he has employed it very skilfully. Actual spring balances were in existence long before in small machines for testing paper, cloth and wire; in 1890 Martens designed a 50-ton machine having a steel bar instead of a spring and Kennedy and Ashcroft had employed a similar device in 1886. Dalby's form is superior to the earlier ones because the inertia of the moving parts is reduced to a very small minimum and the recording, being photographic, does away with the unavoidable friction of pencil recorders. Diagrams may be taken in less than two seconds from start to break.

Extensometers.—Elastic deformations are usually so small that delicate instruments are required in measuring them. Fig. 3 shows in

FIG. 3.

bare principle several types of extensometers or extension-measures; for more detailed information consult the works by Martens, Johnson and Unwin cited above, and also Morrow, 'Measurement of Strains' (in Proc. Inst. Mech. Eng., April 1904); Dalby's photographic extensometer is described in the references already given. In the direct form, Fig. 3, two brackets are clamped to the specimen bar at a fixed distance apart. The stretch of this length is found by noting the separation between the end of a micrometer screw on the upper clamp and the end of a fixed rod on the lower. In

Ewing's extensometer the stretch is read through a small telescope focused on a scale attached to the lower clamp; multiplying levers (not shown here) are used so that readings may be taken to a precision of one part in 50,000. The displacement of the end of the lever in Goodman's instrument is read on a circular scale. The form devised by Martens is extremely delicate and precise but correspondingly difficult to calibrate and to use. A double knife-edge carrying a mirror *M* is supported between the test piece and a stationary or idle rod; relative motion due to stretching tilts the mirror and the angular deflection of a ray of light reflected by it is measured on a scale. Several recording extensometers have been used but the best is that of Dalby.

Shape of Test Pieces.—Elastic properties and strength depend on the shape and size of the test specimen for several reasons. Local stresses due to clamps and grips have greater disturbing effects on small pieces than on large; rolling, machining, etc., produce a surface layer which, like the capillary film on liquids, has properties different from those within the material; blow-holes, minute cracks and particles of foreign substance are relatively larger in smaller specimens; stress tends to concentrate itself at corners, edges, abrupt changes in section and internal cavities so that in a test piece having such peculiarities it is difficult to learn what stress really acts; the planes or surfaces of separation between the molecular crystal groups which are known to exist in even the most homogeneous metals are oriented differently throughout the mass as a result of which two specimens cut from the same body show somewhat different properties. The differences which have been observed between the strengths of long and short round bars cut from the same stock are due largely to lack of homogeneity. Chaplin (in *Van Nostrand's Engineering Magazine*, December 1880 and in Proceedings Engineers Club, Philadelphia, March 1882) has calculated them by means of the theory of probabilities. It is evident, therefore, that tests give comparative results at best. The American Society for Testing Materials accordingly specifies a piece about 18 inches long and two inches in diameter, the middle nine inches being turned to a diameter of one and a half inches and the three cylinders thus formed running smoothly—without shoulders—into one another. The British Standards Committee recommends a cylindrical bar of a length equal to nine times its diameter, extension to be measured on a middle length of not less than eight diameters. Numerous experiments, especially those by Bauschinger and Martens, have shown that the relations between shape and strength follow closely the law suggested by Barba (*Memoirs de la Soci  t   des Ing  nieurs Civils*, 1880, I, p. 682): Under identical conditions geometrically similar bodies of the same material suffer similar deformations under the same stresses. 'Identical conditions' are difficult to realize in practice. An approximation to Barba's law will obtain if the ratio of the length of a bar to the square root of its section area is constant; a length of 20 to an area of π would be convenient as a standard but is considered to be too expensive to prepare for use in commercial tests.

Stress-strain Diagrams.—Hooke's law is only a partial statement of stress-strain relations and sometimes does not apply at all. The behavior of wrought iron and structural steel under tension in the testing machine is exhibited graphically in Fig 4 which is exag-

FIG. 4.

gerated in order to show characteristic peculiarities. Compression tests are not satisfactory from a strictly scientific standpoint: long specimens tend to bend or buckle and in short blocks the local strains produced at the ends manifest themselves too strongly even when the compression plates are well lubricated—as they usually are not. Up to a certain point P stress is proportional to strain and the graph is a straight line of which the modulus E is the slope; the slope seems to be unaffected by cold-working the material whence Rosenhain concludes that E depends more on the nature of the atoms themselves than on their arrangement. P is the *proportionality limit* and marks the point beyond which Hooke's law ceases to hold; the material may or may not be perfectly elastic within this region or beyond it. The limit of perfect elasticity—briefly, the *elastic limit*—depends on the accuracy with which small extensions can be measured and very largely on the previous history of the material. (Consult the discussion by Bairstow, Phil. Trans. Roy. Soc. 1912). For practical purposes P may be regarded as coincident with the elastic limit. At P , which of course is not a sharply marked point, the locus begins to curve downward until Y , the *yield point*, is reached; Y is always beyond the elastic limit. All the strains up to Y develop simultaneously with the stresses; beyond Y they do not attain their full values until considerable time has elapsed. This plastic flow or slow growth of strain under constant stress has been called 'creeping' by Ewing; when the stress is removed the strain creeps back but does not wholly disappear. This lagging in the diminution of strain is named *hysteresis* and belongs to the group of phenomena associated with the elastic after-effect; see the reference above. Plastic flow occurs with hardly any increase of volume; during elastic strain the cross sections change according to Poisson's law. The serrated part of the curve, Y to A , occurs only in wrought iron and mild steel; it indicates unstable readjustments in crystal grouping. Real ductile distortion begins at A , and a waist of hour-glass shape starts to form near the middle of

the test piece. If the stresses are calculated by dividing the load by the *original cross-section* the curve runs through M to R the point of rupture. This gives *nominal stresses*; the actual stresses determined by using the actual area of section—must be computed as they cannot be plotted by automatic recorders.

Other materials show characteristically different curves. With increase of carbon, nickel, or chromium the serrated line in the strain diagram of steel smooths out and plastic ductility sets in immediately after the yield point; the curve from A onward is different enough in each case to indicate quite closely the nature of the metal under test. Neither cast iron (in tension or compression) nor concrete (in compression) follows Hooke's law. Some writers infer from this that these materials are never perfectly elastic. This is unjustifiable because there is at present no known connection between perfect elasticity and the proportionality of stress and strain. Conclusions drawn from experiments on cast iron are unsatisfactory on account of the existence of initial stress due to sudden cooling. Rolled aluminium does not obey Hooke's law but is decidedly elastic. For materials such as these Bach and Schüle have proposed the empirical law

$$p^n = Es$$

where n is a constant equal in the case of cast iron in tension to 1.07.

Stress Relations.—In most engineering problems the stresses at any point in a body are all parallel to one plane and are, therefore, called *plane stresses*; we shall limit the discussion to this case. Stress on one plane at any point produces stress on every plane at that point. Fig. 5 shows an infinitesimal ele-

FIG. 5

ment in the most general state of plane stress, there being by assumption no stresses perpendicular to the paper. The stresses on any face, for example the left, are p_1 normal, and q_1 tangential; the corresponding forces are $p_1 dy$ and $q_1 dy$ if the thickness is unity; the other stresses are assumed to act as in the diagram. As the element is in equilibrium unless vibrations occur the sum of the moments of all forces—not stresses—about a central axis normal to the paper must vanish; although the stress may vary from point to point it is constant over an infinitesimal area. Hence

$$\frac{1}{2}(q_1 \pm q_1') dx dy = \frac{1}{2}(q_1 + q_1') dy dx.$$

In the limit $q_1' = q_1$ and $q_2 = q_1' \therefore q_1 = q_2$ or: shear stress on any plane through a point is always accompanied by equal shear stress on a perpendicular plane through that point, both stresses acting away from or toward the edge of intersection and normal to it. This is Cauchy's theorem.

If the stresses on two planes X and Y at a point P are known as in Fig. 6, the stress on

FIG. 6.

any other plane *through that point* can be found. Pass any plane at an infinitesimal distance from P and take the wedge thus formed as a free body. There will in general be normal and shear stresses p' and q' on the oblique plane. If the hypotenuse of the wedge has an area dA the forces on it will be $p'dA$ and $q'dA$; the horizontal force on the vertical face is $p_y dA \sin \theta$, and so on for the other forces. By resolving along p' and q' respectively and replacing functions of θ by functions of 2θ we get

$$p' = \frac{p_x + p_y}{2} - \frac{p_x - p_y}{2} \cos 2\theta - q \sin 2\theta \dots (1)$$

$$q' = \frac{p_x + p_y}{2} \sin 2\theta - q \cos 2\theta \dots (2)$$

which remain unchanged when dA becomes zero. They are the stresses at P on any oblique plane of angle θ .

When $q' = 0$

$$\tan 2\theta = \frac{2q}{p_x - p_y} \dots (3)$$

which, being satisfied by the two values θ and $\theta + 90^\circ$, shows that there are always two orthogonal planes free from shear stress. They are called *principal planes* and the pure normal stresses on them *principal stresses*. If (3) is substituted into (1) the principal stresses, say p_1 and p_2 , are found to be

$$p_1, p_2 = \frac{p_x + p_y}{2} \pm \sqrt{\left(\frac{p_x - p_y}{2}\right)^2 + q^2} \dots (4)$$

By putting $dp'/d\theta$ from (1) equal to zero we get the important fact that the principal stresses are the largest and smallest normal stresses in the body at P .

While there are always two pure normal stresses, pure shear exists only under special conditions. Take, instead of X and Y , the principal planes as the planes of reference. Then in (1) and (2) q drops out, p_x and p_y must be replaced by p_1 and p_2 , and θ stands for the angle between the oblique plane and one of the principal planes;

$$\therefore p' = \frac{p_1 + p_2}{2} - \frac{p_1 - p_2}{2} \cos 2\theta \dots (5)$$

$$q' = \frac{p_1 - p_2}{2} \sin 2\theta \dots (6)$$

The condition for pure shear on the oblique plane is $p' = 0$ from which

$$2\theta = \frac{p_1 + p_2}{p_1 - p_2};$$

this is impossible unless p_1 and p_2 are opposite in sign or unlike in sense. Hence pure shear exists only when the principal stresses are unlike. If they are unlike but numerically equal,

$\theta = 45^\circ$. But pure shears are not in general the greatest or least shears. It is evident from (6) that maximum and minimum shears occur when $\theta = 45^\circ$; in other words, the planes of maximum and minimum (greatest numerical) shear lie at 45° to the principal planes. The largest shear stress is, therefore,

$$q' = \frac{1}{2}(p_1 - p_2) = \frac{1}{2}\sqrt{(p_x - p_y)^2 + 4q^2} \dots (7)$$

The effect of a stress p is a strain p/E in the direction of P and, by Poisson's law, a lateral strain p/mE perpendicular to P ; they are opposite in sign. Consequently when a block is acted on by tensions p_1 on one pair of opposite faces and tensions p_2 on a pair perpendicular to the first, the resultant strain E_1 along p_1 is

$$E_1 = \frac{p_1}{E} - \frac{p_2}{mE} \dots (8)$$

A single stress equal to Ee_1 acting alone in the direction of p_1 will produce the same strain in this direction as both p_1 and p_2 ; in this respect it is equivalent to them and is called the *equivalent simple stress*.

Working Stress; Elastic Failure.—The mechanics of elastic bodies is of limited value in rational designing and serves only as a refined rule of thumb until it is decided how large a stress or strain a material can safely resist, how large a stress causes ultimate rupture and finally whether failure is produced by normal or shear stress or by some combination of them. Researches initiated by Wöhler in 1870 and continued by Bauschinger, Reynolds and Smith (Phil. Trans., Roy. Soc., 1902, p. 265), Stanton and Bairstow (Proc. Inst., Civil Engineering, 1906, Vol. CLXVI, p. 78), and others have shown that alternating stresses (tension to compression) well below the elastic limit may produce rupture when repeated often enough. A familiar illustration of this phenomenon is that springs do not last forever, although they might never be stressed beyond the so-called "safe" limit. It used to be believed that these reversals caused the material to crystallize or become granular. This is now known to be incorrect; all inorganic bodies are crystalline under the microscope, and reversed stresses, or even fluctuating ones always of the same kind, weaken the material by causing grinding and abrasion on planes of cleavage. Investigations solely with the aid of testing machines will throw probably little light on the subject. The most fruitful results are undoubtedly to be looked for in the comparatively new field of *metallography*. This is concerned with the microscopic examination of internal structure. The first attempt to bring the microscope to the aid of the testing machine was made in 1864 by Sorby of Sheffield, whose work, however, remained unknown until it was independently taken up again by Martens in Germany and Osmond in France. The subject is too large to be discussed in a short article. Consult Mellor, 'Crystallization of Iron and Steel' (1905); Rosenhain, 'Introduction to Physical Metallurgy' (1917), and Humphrey, 'Metallography of Strain' (1919).

Both strength and stiffness need to be considered in designing. No structural member may yield or give more than a certain amount apart from the question of strength. For instance, if a floor beam sags by an amount

greater than about one-third per cent of its length a plastered ceiling under it will crack. Questions of rigidity or stiffness are decided by means of mathematical formulas derived either from the principles of mechanics or empirically. They are based on Hooke's law and on the assumption that the elastic limit is not exceeded. The usual method of checking them is to compare calculated with experimentally found deformations; the calculated stresses are difficult to verify because we have no direct method of measuring stress within a body. However, use has been made of the well-known fact discovered by Brewster in 1815 that an isotropic transparent medium is made doubly refracting by stress and breaks plane polarized light into orthogonal components; likewise, circularly polarized waves become elliptically polarized. Wilson, Carus (in *Phil. Mag.*, Vol. XXXII, 1891, p. 481); Hönigsberg (in *Zeitschrift öst. Ing. Verein*, 1904, Nr. 11); Mesnager (in *Annales des Ponts et Chaussées*, Fasc. iv, 1913) and Coker (in *Engineering*, Vol. XCI, p. 1), examined the optical properties of various structural elements made of celluloid and glass and found a remarkably close agreement between theory and fact. Of the many books dealing with the formulas of the mechanics of materials the most complete are Morley, 'Strength of Materials' (1908 and later editions), and Bach, 'Elastizität und Festigkeit' (5th ed., 1905).

The working stress is the greatest stress to which a member of a structure or a machine is subjected during use or operation. If it exceeds the elastic limit there may occur permanent deformations not allowed for in the design, change of properties of the material, and when the stresses alternate or vary, ultimate failure. Indeed, the working or safe stress must be taken considerably below the elastic limit to allow for deterioration due to wear, unavoidable imperfections in workmanship and manufacture, lack of uniformity of material, accidental overloading, but *not for poor design*. As it is difficult under commercial conditions to determine the rather ill defined elastic limit it is customary to state the safe stress as a certain fraction, $1/n$, of the breaking stress; n is called the *factor of safety* and is determined by experience. According to the experiments of Wöhler and Bauschinger on steady, fluctuating, and alternating loads, the safe stresses are in these cases roughly in the ratios 3:2:1, which are, therefore, taken as a guide in determining the factors. The building laws of many cities in the United States specify definite, safe stresses instead of factors of safety. For recent data consult Marks, 'Mechanical Engineers' Handbook' (1917); Merriman, 'American Civil Engineers' Pocket Book' (1916).

A material is simple tension or compression, or simple shear is considered to be overloaded when the corresponding safe stresses, as defined above, are exceeded. The immediate cause of failure in the case of compound stress—a number of stresses acting simultaneously—is still a matter of dispute. A material fails when the yield point is reached. Lamé assumed that the largest principal stress produced yielding; this theory is sometimes called after Rankine because he gave it considerable authority by

using it in his 'Applied Mechanics' (1858), and it is generally followed by American and English engineers. In it the effect of the other principal stresses is disregarded, which implies that a block under compression on top and bottom is just as strong as it would be if it were prevented from expanding laterally. Poncelet and Saint Venant believed that excessive *strain* caused failure, i.e., stress is harmful only in so far as it produces molecular separation. From this point of view, the equivalent simple stress must not exceed the working stress. Coulomb, Tresca and G. H. Darwin proposed the theory that the difference between the principal stresses, i.e., the greatest shear—eq. (7) above—is a measure of strength. Recent experiments have given some confirmation to it, at least for ductile metals. Consult Guest, 'Strength of Ductile Materials under Combined Stress' (in *Phil. Mag.*, 1900, Vol. L); Hancock, 'Effect of Combined Stresses' (ib., 1906, Vols. XI, XII); Scoble, 'Strength of Ductile Materials under Combined Stress' (ib., 1906, Vol. XII). The latest theory is that of Mohr (in *Zeit. Verein d. Ing.*, Vol. XLIV, 1900, p. 1524, Vol. XLV, 1901, pp. 4, 740), the essential hypotheses of which are: (a) failure depends only on the normal stress on the surface of rupture; (b) the surface of rupture is normal to the planes of greatest and least principal stresses [for space stresses there are three principal planes], i.e., is parallel to the principal plane of intermediate stress and is independent of that stress.

In the absence of conclusive experiments it is necessary to design independently for greatest shear, greatest normal stress and greatest equivalent simple stress; this errs on the side of safety. Metallographical researches have shown such great differences in the molecular structure of materials that a complete theory of elastic strength will probably have to take structure into consideration instead of, as now, dealing only with the geometric arrangement of the stress vectors on the one hand and the stress-strain curve on the other.

RICHARD F. DEIMEL,
Assistant Professor of Mechanics, Stevens Institute of Technology.

STRENUOUS LIFE, The, a collection of 13 essays and addresses on various subjects by Theodore Roosevelt, published in 1900. The book takes its title from the first of the series.

STREPTOCOCCUS. See Coccus.

STRETFORD, strēt'fōrd, a town in Lancashire, England, four miles southwest of Manchester. Among its chief features are a public hall, municipal offices, a free library, charitable institutions and botanical gardens. It has numerous cotton factories. Pop. about 50,000.

STRETTON, strēt'on, Hesba, the pseudonym of Hannah Smith, English novelist, who began writing fiction in 1859. Among her 40 or more books are 'Bedes' Charity,' by which she is best known; 'The Doctor's Dilemma'; 'Hester Morley's Promise'; 'Soul of Honor.' Her works are deservedly popular and have been translated into all of the European and several of the Asiatic languages.

STRIÆ, grooves or scratches on rock. These are commonly produced by glaciation, as a result of boulders frozen into the ice

scratching against bed-rock. As the boulder may break loose in the ice and turn its position, and then freeze fast again, boulders may be striated in several directions. More than one set of striæ on the bed-rock, however, means one advance of the ice following another from a different direction. Striæ are also produced by faulting. See **FAULT**; **SLICKENSIDES**; **GLACIER**, and section on *Glaciers* in article on **GEOLOGY**.

STRICKLAND, strik'land, Agnes, English historical writer: b. Reydon Hall, Suffolk, 19 Aug. 1806; d. there, 8 July 1874. She was one of five sisters, all of whom were writers. Her first work, in which she was aided by her sister Susannah, was a volume of 'Patriotic Songs,' followed by 'Worcester Field,' a historical poem. Her later works were 'Queen Victoria from her Birth to her Bridal' (1840); 'Historic Scenes and Poetic Fancies' (1850); 'Lives of the Bachelor Kings of England' (1861); 'Lives of the Seven Bishops' (1866); 'Lives of the Tudor Princesses' (1868). Her best works are 'Lives of the Queens of England' (12 vols., 1840-48), and 'Lives of the Queens of Scotland' (8 vols., 1850-59); 'How Will It End?' (1865); 'Lives of the Last Four Stuart Princes' (1872). In these her sister Elizabeth collaborated, but at the latter's own desire her name was not revealed as co-author with Agnes. Miss Strickland's work is very readable and has been exceedingly popular, but belongs to a school of historical writing now gone by. Consult 'Life' by her sister Jane (1887); and 'Pearls and Pebbles' by Mrs. Catherine P. Traill, another sister (London 1894).

STRICT CONSTRUCTIONISTS, in American politics, those who believe the Federal government has no rights nor powers which are not expressly granted by the Constitution. The Anti-Federalists (q.v.) were strict constructionists. The broad constructionists, on the contrary, believe that a liberal view of the power and intentions of the Constitution should be held and that the Federal government should not be bound by an inflexible law preventing the natural growth of the democratic institutions of the country. The strict and the broad constructionists have come into conflict often in the history of the American Republic, the most notable occurrence being in the struggle over slavery. The strongest supporters of the strict-construction point of view have been the Anti-Federalists and the Democratic party, who were opposed by the Federalists, National Republicans, Free-soil and modern Republican parties. Of late years the Strict Constructionists have lost ground so rapidly that their contentions no longer form an issue in American politics.

STRICT OBSERVANCE, Friars of. See **ORDERS, RELIGIOUS**.

STRICTURE, a morbid contraction of a mucous canal or duct of the body, as the urethra, œsophagus, or intestine. When the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory. The first form is due to a thickening of the walls of the urethra in consequence of organic deposits, and is hence termed organic stricture. The second may be due either to local inflam-

mation or congestion, or to abnormal muscular action, the first of these varieties being inflammatory or congestive stricture, and the second spasmodic stricture, of which the last named seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture, inflammation of the canal, and injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. It is only in exceptional cases that a stricture results from inflammation of the urethra. Stricture in the second case arises from such causes as falling across spurs, scaffolding, ladders, etc., or from some sharp object which punctures the perinæum.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal behind the seat of the stricture at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted, and as the disease advances it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge the urine often induce tenesmus. As the case advances the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand. Attacks of complete retention of urine occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a catheter or bougie to ascertain whether an organic obstruction exists, whether one or more strictures are present, and their calibre. The treatment of organic stricture is chiefly mechanical. It is sufficient to restore the natural calibre of the canal so far as this can be safely effected, and to maintain this patency after it has been established. Spasmodic stricture usually occurs as a complication of organic stricture or of inflammation of the mucous membrane, but may arise from an acrid condition of the urine, from the administration of cantharides, turpentine, etc., and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible and the use of a hot bath. The inhalation of chloroform sometimes gives immediate relief. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The treatment is much the same as that for retention of urine. Consult Rowlands, R. P., 'The Operations of Surgery' (New York 1915).

STRIFE, by John Galsworthy. Nothing is more striking in Galsworthy's work as a dramatist than the skill with which he combines the functions of the artist and the social critic without prejudice to either. In all but two of his plays he has chosen for his theme some one of the outstanding problems of modern social organization and clothed it in dramatic form of compelling interest. In 'Strife' it is the conflict between capital and labor as exemplified in a prolonged strike at the Trenartha Tin Works. The directors of the company have been summoned down from London for a conference with the men and the action takes place during a single afternoon. The company is losing money; the men and their families are starving; both are ready to come to terms but their indomitable leaders, old John An-

thony, founder and president of the company, and David Roberts of the workmen's committee, will not hear of compromise. Both men are fighters and both are fighting for a principle; it is a clear-cut "conflict of wills" such as few dramas present. When Anthony talks to his frightened directors we feel that nothing can balk that iron will. But Roberts' passionate appeal to his fellow workers to hold out in order that their sacrifices and suffering shall not be in vain is still more moving and no less forceful. Although the struggle finally ends in compromise between employers and men, the tense emotional interest is maintained to the very end. Roberts comes from the death bed of his wife to fling defiance at the board only to learn that the agreement has just been signed, and he and Anthony face defeat together with a like scorn of their weaker followers and a reluctant sympathy and respect for each other. While these two are the chief protagonists, Galsworthy uses no less than 30 speaking parts to fill in his picture and at least half of these are clearly defined individual characters, yet his canvas is neither crowded nor confused. This is largely due to his masterly command of natural and characteristic dialogue. His personages are never mere mouthpieces for his own ideas but speak their own thoughts in their own language.

An interesting comparison suggests itself with certain plays of other nationalities based on the same theme, such as Björnson's 'Beyond Human Power,' Hauptmann's, 'The Weavers,' Bergstrom's, 'Lyngaard & Co.,' Mirbeau's, 'Les Mauvais Bergers.' Lack of space forbids comparison in detail but it is noticeable that all these plays culminate in a scene of mob violence whereas Galsworthy achieves the effect of violent emotion and strained nerves by more subtle means.

'Strife' was first produced in a series of matinees at the Duke of York's Theatre in London in March, 1909. The first American production took place at the New Theatre, New York, in November of the same year.

STRIKE. See DIP.

STRIKES AND LOCKOUTS. A strike is a cessation of work on the part of workingmen to enforce their demands against the employer or to resist demands and rules made by the employer; a lockout is a cessation of work on the employer's initiative to enforce demands against his employees. Strikes are essentially a feature of the modern industrial organization; they developed gradually with the progress of industry and organization by unions of workingmen, reaching their height in the 19th century; the largest and most important strikes having occurred since 1870. While it is true that strikes have increased as the modern labor union has grown, yet it is also true that many strikes occur in unorganized or poorly organized industries; and it has usually been true that a young organization is much more apt to enter upon strikes as a means of testing its strength and enforcing its demands than an old organization. The older and stronger a labor union grows,

as a rule, the more conservative it is in regard to strikes, and the less likely to order a strike for petty and insufficient cause. Nevertheless strikes are a recognized and important part of trade union policy. They are defended by trade unions on the following grounds; they are absolutely the only means which labor has of enforcing its demands in case argument and arbitration fail and afford the most practical means of controlling the supply of labor for the benefit of labor; whether a strike succeeds or not it attracts public attention to the question at issue and may lead to the satisfactory solution by the pressure of public opinion; they mark the line beyond which labor will not be forced in the reduction of wages or enforcement of unjust demands; the very possibility of a strike which inflicts an injury that the employer desires to avoid often prevents the attempt to enforce demands which employers know would be unwelcome to labor. The more radical view of a strike is based on the doctrine that the interests of labor and capital are necessarily antagonistic; that a strike, therefore, is an attempt to advance the interests of labor as against those of capital and is from labor's point of view entirely right and justifiable; it is a sort of advance skirmish in the war of interests between labor and capital and useful as winning some definite advantage to labor or of proving the strength and vitality of the labor movement and inflicting a more or less serious injury on capital. Against the policy of strikes it is urged that they cause heavy loss to both the labor and capital lying idle; that with their modern magnitude they seriously affect the whole industrial life and inflict an injury upon the general public; and that the points gained by labor are not commensurate with the cost of the strike. It must be remembered, however, that a strike is essentially a war and that many of the evils of war attend it; whereas if it be based upon a principle of justice it can be defended upon the same grounds as a war.

Causes of Strikes.—The chief causes of strikes are centred about the wage question; the largest number of strikes in the decade of 1881-1900 were for increase of wages; other important causes are for reduction of hours, against reduction of wages, for the recognition of the union and for the enforcement of union rules. The following statistics are taken from the report of the United States Bureau of Labor Statistics:

LEADING CAUSES OF STRIKES.

Cause	1915	1916
Increase of wages.....	355	1,031
Increase of wages and reduction of hours.....	156	374
Reduction of hours.....	73	107
Against reduction of wages.....	32	97
Sympathetic.....	16	32
For union recognition.....	66	257
For increase of wages and recognition of union.....	28	119
Recognition, wages and hours.....	11	68
Discharge of employees.....	67	121
Employment of non-unionmen.....	55	70
General conditions.....	37	55
Miscellaneous.....	634	826
Totals.....	1,420	3,157

Of the above strikes, 15 in 1915, lasted over 200 days and 16 in 1916. In 1915 24 lasted 92 to 199 days and 79 in 1916. In 1915 48 lasted 50 to 91 days and 106 in 1916; while in 1915 74 lasted 25 to 49 days and 182 in 1916. The lockouts in 1915 totaled 173 and in 1916, 108. The States most affected by the disturbances in these years were New York, Pennsylvania, Massachusetts, Ohio, New Jersey, Illinois and Connecticut in the order named. The trades most affected were metals, mining, building, textiles, transportation and clothing.

Sympathetic Strikes.—The sympathetic strike is one undertaken by a body of workmen who have no special grievance of their own, in behalf of another body of workers on strike. It developed about 1880 and was based upon the workingman's recognition of the principle of the "solidarity of labor"; the principle that labor's interest are everywhere essentially the same and that an injury to one is an injury to all. The sympathetic strike is usually undertaken by workmen employed by the same employer as the original strikers; or against an employer in some direct relationship with the employer of the original strikers, as competitor, buyer or seller or co-operating. In this way their action has direct economic effect on the question at issue, as well as the more general and less tangible effect of "sympathy." Sympathetic strikes involve the dangers of violence and the weakening of a powerful organization, by the keeping idle of a body of men not so closely bound together nor so individually interested as if the strike directly concerned their personal welfare. Nevertheless, the mere fact that sympathetic strikes are undertaken is a proof of the development to some extent of a more enlightened and far-seeing self-interest, which often amounts to altruism, among workmen. In connection with sympathetic strikes, the question of the universal strike may be mentioned; a universal strike in all departments of industry to obtain some special demand is naturally the logical development of the sympathetic strike. The universal strike has never been a problem for serious consideration in the United States; but on the Continent, where the labor movement is largely directed by the Socialists, it has been frequently agitated, especially in France; and was used as a powerful weapon in Belgium in 1893 to force the government to the adoption of the principle of universal suffrage.

Methods of Conducting a Strike; Picketing, etc.—The ordinary method of beginning or "ordering" a strike is by vote of those who are concerned; in the case of organized labor, the matter is usually referred to the national officers for an attempt at settlement, or approval of the action of the strikers, the latter securing the support of the whole organization. Often in large strikes, or in the case of partially organized industry appeal for financial aid and moral support is made to labor in general or to some large general organization like the Federation of Labor. The interest of the strikers is kept up and public interest aroused by meetings, speeches and the circulation of literature. The most important consideration is to prevent the "breaking" of the strike either by defections from the ranks of the strikers or by the bringing in of more workmen to take their places. The method generally adopted to

prevent the latter is known as picketing, that is, the placing of some men near the establishment involved in a strike to speak to any who may come to take the strikers' places and to dissuade them from so doing. This has led often to threats and intimidation on the part of the pickets; and sometimes to violence. The result has been that the tendency of judicial decisions is to declare picketing illegal, or to so strictly limit the rights of the pickets as to make their work practically useless; a few States have declared picketing illegal by statute. Another method of preventing workmen from taking strikers' places is by large general meetings near the establishment involved, or at the place where workmen are brought into the town; this, however, is a more dangerous method than picketing, as it is often the means of collecting a large and irresponsible crowd, quite beyond the control of the leaders of the strike. Violence in a strike probably works more harm to the strikers than to any other thing; it arrays public opinion against them and brings against them the forces of government and the military. Trades unionists everywhere recognize this fact and invariably denounce violence whenever it occurs; the violence is often committed by persons having nothing to do with the strike, but taking the opportunity to do mischief and when committed by the strikers has not the approval of organized labor. It is often charged that strikers have sometimes been provoked to violence by agents of the employers in order to give better cause for breaking the strike; such charges are difficult to prove, but it is generally the opinion that such cases have occurred in the coal fields at least, if not elsewhere. One of the methods of fighting a strike is the injunction. The first time the injunction was of marked importance was in the Pullman strike of 1894, when the officers of the American Railway Union were enjoined not only from threats, intimidation and encouraging violence, but also from aiding or "persuading" any persons to strike. Injunctions since then have been frequently used and are often very severe against the strikers; the terms of most sweeping injunctions, however, have usually been changed in favor of the workmen if the matter was brought into court by the strikers.

History and Statistics.—The first strike on record in the United States is that of the bakers in New York in 1741; the strikers were brought before the court on a charge of "conspiracy," but not convicted; the shoemakers of Philadelphia struck for increase of wages in 1792 and three times subsequently before 1800 and were in every case successful; in 1805 the shoemakers again on strike were convicted in court on a charge of forming a "combination to raise wages," and were fined eight dollars a head. Up to the Civil War strikes were comparatively few and small in extent; they were mostly for increase of wages or reduction of hours. After the Civil War the strikes increased in number and in importance; in 1872 occurred a succession of strikes in the building trades for the eight-hour day, which were mostly successful. In 1877 was the great railroad strike, begun by the firemen of the Baltimore and Ohio against a reduction of wages; it spread to the Pennsylvania, the Erie, the Lake Shore and numerous other important

railroads and involved a large amount of violence and bloodshed, particularly in the region about Pittsburgh. Numerous strikes have taken place in the coal fields and have as a rule been attended with more or less bloodshed; though many have failed, some have been successful and the miners have gained some important points. Prominent among the coal strikes are those in the bituminous coal fields in 1894 and 1897, the latter resulting in a fairly satisfactory wage scale; and those in the anthracite coal fields of 1900 and 1902, that of 1902 threatening a coal famine and being adjusted by a commission appointed by the President of the United States. Among other noted strikes was that at Homestead in 1892 and the Pullman strike of 1894; the latter was a sympathetic strike undertaken by the American Railway Union in behalf of the employees of the Pullman Company, their purpose being to boycott the Pullman cars and prevent the railroads from hauling them; traffic was seriously delayed and considerable violence occurred, especially in Chicago; the national troops were brought into use by President Cleveland, though against the protests of the governors of Illinois and other States. The injunction, before mentioned, caused the imprisonment of the president and other officers of the American Railway Union, and the strike was a failure, though for the first few days it promised success.

The statistics of strikes for 1881-1900 show that there were 22,793 strikes, involving 117,509 establishments and 6,105,694 workingmen; of this number 50.77 per cent were successful; 13.04 per cent partially so, and 36.19 per cent failed. The greatest per cent of strikes which were successful were for reduction of hours, overtime pay, etc., 59.3 per cent; 53.2 per cent of those for increase of wages were successful and 18.2 per cent partially so; and 50.8 per cent of those for recognition of the union were successful. The statistics of lockouts show 42.93 per cent successful and 6.28 per cent partially so.

The first decade of the present century was marked in the United States by many strikes for the reduction of hours. Eight hours had become customary in many trades and those unions not enjoying it made concerted efforts to attain shorter hours and generally won. Among the most severe and protracted of these strikes was that of the International Typographical Union and affiliated organizations in the printing trade in 1906. This was bitterly fought in every large city in the country and was not entirely won for two or three years. The losses to the employers, unions and the public, both direct and indirect, were estimated at \$25,000,000. As a result the Printers' League was organized by employers in the book, job and publication branch of the industry and this body, together with the American Newspaper Publishers' Association, has since endeavored to settle all difficulties by arbitration and largely succeeded.

The railroad trainmen were among the last to secure eight hours, the companies contending that the character of railway work was such that men had to continue until the trains arrived at destinations, so no hour schedule was possible. The men demanded overtime rates for work beyond eight hours and a nationwide strike was called for 4 Sept. 1916. At

the time the railways were glutted with business and obviously a prolonged railroad strike meant paralysis to more than half the industries of the country, and lack of both food and fuel in many places. President Wilson demanded Congressional legislation to meet the situation and the Adamson Eight-Hour Act was rushed through and put into effect 1 Jan. 1917.

The War Situation.—In 1917 there were numerous demands made on employers for higher wages, growing out of the presumed great profits of manufacturers working on war orders. The strikes were mostly settled by paying the wages demanded and rapid increases of wages followed. When America entered the war, the reduced number of workers enabled workmen in many instances to dictate their pay and this with a general understanding that strikes were unpatriotic, reduced the strike evil for the time being. Owing to the scarcity of domestic commodities, however, the advance in prices and consequent high cost of living, the demands on employers for increased wages became more urgent during 1919 and resulted in many serious strikes, lockouts and closing of factories. Arbitration in many cases was refused and the strike remedy unfortunately was resorted to with ever-increasing frequency. See AMERICAN FEDERATION OF LABOR; TRADE UNIONS.

STRINDBERG, strind'bër'ig, August, Swedish novelist, dramatist and publicist: b. Stockholm, 22 Jan. 1849; d. Stockholm, 14 May 1912. In his autobiographical novel 'The Son of a Servant' he emphasizes the dual social nature of his origin and attempts to derive his conflicting and unstable position on many questions from it. His mother (d. 1862) was of the poorest classes, his father of middle-class business position (steamship agent, d. 1883). From earliest childhood his life was one long struggle with his associates, teachers, parents, friends and rivals, differing, however, from that of other persons in that the consciousness of struggle is always present in his work; he never for a moment pretends that life is anything else. After passing through a number of parochial and preparatory schools, the tortures of which he has described in 'The Son of a Servant,' he went to the University of Upsala in 1870, where his experiences were not less unpleasant. 'I Rom' (In Rome) is a tragedy of this year, dealing with the experiences of the sculptor Thorvaldsen. 'Den fredlöse' (1871) is a one-act tragedy with a viking subject, in saga language. His first important play, written after Strindberg had turned to literature and left the university (1872), is 'Master Olof' (English trans., New York 1915), a prose drama of the Swedish Reformation (a version in verse was written 1878), full of youthful rebellion and pessimism. The play was written in the skerries of the Swedish Baltic, which were to remain for many years a source of stimulus and inspiration to Strindberg. A collection of sketches of student life at the university 'Fran Fjårdingen och Svartbäcken' (1877) is realistic and boisterous to the extreme, qualities which are emphasized in Strindberg's great satirical novel on all of Swedish society, 'The Red Room' (1879, English trans., New York 1913), which with all its intimate warmth of narration, remains an icy

and supercilious tirade of scepticism, doubt, agnosticism. 'Nya Riket' ('The New Kingdom' 1881) is a criticism of Swedish social life after the parliamentary reforms of 1865. From 1880 to 1885, much of which period he spent in Switzerland, Strindberg was active as a Socialist of revolutionary tendencies; the most striking expressions of this attitude are his collection of propagandist material called 'Upper and Lower Class' (written 1880, first published 1884), and the four short stories published under the title 'Utopier i Verk-ligheten' ('Utopias on Earth,' 1885). 'Sam-vetskval' ('Pangs of Conscience'; two translations, Chicago 1915, and New York, in *The Call*, 1916) is the best of the latter; it is a powerful anti-militaristic tale of the Franco-Prussian War of 1870. His writings after that period display a growing conservative, even, on occasion, fanatically reactionary tendency. This evinced itself in his violent hatred of women, in general, although he was by no means inaccessible to their charms, and, toward the end of his life, in a predilection for mystical and occult study, and for mystic and supernatural elements in his later plays. In 1885, when he published the 30 short stories known as 'Married' (English trans., New York 1912), his attitude toward women was not that of the misogynist, although his introduction to the collection indicated his belief that the economic and social conditions of the age were constantly driving women into a more and more selfish and immoral position. His most delicate and human touches are to be found in this collection. In the dramas written about 1890, misogyny is already a dangerous obsession with Strindberg, leading him to produce such impressive perversions as the dramas 'The Father,' 'Countess Julia,' 'Creditors.' By 1890, Strindberg had completely passed out of his socialistic stage and into that of anarchic individualism, strongly influenced by Nietzsche. In that year appeared his novel of fishermen's life: 'I hafsbandet' (two English translations: 'By the Open Sea,' New York 1913; 'On the Seaboard,' Cincinnati 1913), in which the hostility between the educated and the lower classes is concentrated into a conflict with a tragic outcome, the woman taking the side of the lower classes against the intellectual aristocrat.

Throughout his life Strindberg was a diligent scholar and undertook painstaking, though not always original research in many fields, particularly Kulturgeschichte, philology, chemistry, sociology and ethnology. His great historic work on the history of the Swedish people ('Svenska Folket') appeared in 1880 and the studies for it are the basis of the collection of historical short stories 'Svenska Öden och Äventyr' (1880-90) and of a long series of historical dramas: 'Folkungasaga,' 'Gustaf Vasa,' 'Erik XIV,' 'Gustaf Adolf,' 'Charles XII,' 'Engelbrekt,' 'Christina,' 'Gustaf III,' etc. His last plays were peculiarly resigned and gloomy studies of city life: 'Ovåder,' 'Brända Tomten,' 'Spöksonaten,' 'Pelikanen' (all 1907); 'Stora landsvägen' (1909). He attempted to gather all his disjointed opinions, in short articles of a page or two each, with strong reminiscences of Swedenborg, Goethe, Peladan and others, in the 'Blue Books' (1907, 1908, 1912), selections from which will

be found in 'Zones of the Spirit' (New York 1913). Strindberg was thrice married: his first wife was the Swedish actress, Siri von Essen (married 1878; d. 1912; divorced in the '80's); his second wife was the Austrian authoress, Frida Uhl (married 1893; divorced 1896); his third wife was the Swedish actress, Harriet Bosse (married 1901; divorced 1904). Three children also survive him. (See FATHER, THE). Works not already mentioned and collected editions include 'Samlade Skrifter,' ed. Landquist, thus far 55 vols. (Stockholm 1912-18); 'Skriften,' trans. by Schering, thus far 30 vols. (Munich 1906-14); 'Plays,' trans. by Björkman, thus far four vols. (New York 1912-16); 'Easter and Stories,' (Cincinnati 1912); 'In Midsummer Days and Other Tales' (New York 1913); 'The Inferno' (New York 1913); 'The Growth of a Soul' (New York 1913); 'Historical Miniatures' (New York 1913); 'Advent' (Boston 1915). Consult Lind-af-Hageby, L., 'August Strindberg, the Spirit of Revolt' (New York 1913); Björkman, E., 'Voices of To-Morrow' (New York 1912); Esswein, H., 'August Strindberg' (Munich 1908); Paul, Ad., 'Strindberg-Erinnerungen und Briefe' (Munich 1914); 'En Bok om Strindberg' (Karlstad 1894); Uddgren, G., 'Boken om Strindberg' (Gothenburg 1909); Uddgren, G., 'En ny bok om Strindberg' (Gothenburg 1912); Zetterlund, R., 'Bibliografiska Anteckningar om August Strindberg' (a good bibliography, Stockholm 1913).

JACOB WITTMER HARTMANN.

STRINGHAM, string'am, Silas Horton, American naval officer: b. Middletown, N. Y., 7 Nov. 1798; d. 1876. He joined the United States navy in 1809 and served on the frigate *President*. He was promoted lieutenant in December 1814; served on the schooner *Spark* in the Mediterranean Sea in 1815-18; and took part in the war with Algiers. In 1821-24 he was executive officer on the *Hornet* in the West Indies. He was promoted captain in 1841; he served on the *Ohio* during the bombardment of Vera Cruz in 1847. On the opening of the Civil War in the United States he was appointed flag officer of the North Atlantic blocking squadron and was at the capture of the forts on Hatteras Inlet. He was relieved of his command in the fall of 1861 and the following year was made a rear-admiral.

STRIPED BASS, STRIPED SKUNK, STRIPED SQUIRREL, STRIPED SNAKE, etc. See BASS; SKUNK; SQUIRREL; GARTER SNAKE.

STROEBEL, stre'bl, Edward Henry, American diplomat: b. Charleston, S. C., 7 Dec. 1855; d. Bangkok, Siam, 15 Jan. 1908. He was graduated from Harvard in 1877 and from Harvard Law School in 1882 and after practising in New York (1883-85) was secretary of the United States legation at Madrid in 1885-90. He was third assistant secretary of state April 1893, April 1904, Minister to Ecuador April to December 1894, and to Chile 1894-97, and in 1899 was appointed counsel for Chile before the United States and Chilean Claim Commission. From 1898-1906 he was Bemis professor of international law at Harvard. He was granted leave of absence by the University in 1903 to become general adviser to the Siamese government and in 1906 resigned

from the university to become permanent adviser. Among his published writings is 'The Spanish Revolution' (1898).

STROMBOLI, ström'bō-lē, an island of the Lipari or Æolian group, in the Mediterranean Sea, off the northern coast of Sicily. It consists of a lofty volcano, whose cone rises to a height of 3,022 feet and is in constant activity. It was believed by the ancients to be the abode of Vulcan and in mediæval times the entrance to purgatory. The island is fertile and its chief products are cotton, wine, figs and other fruits belonging to this region. It yields besides, sulphur and pumice stone and possesses warm mineral springs.

STROMEYERITE, an ore consisting of sulphides of silver and copper in somewhat variable proportions, occurring in some of the mines of the far West.

STRONG, Augustus Hopkins, American theologian: b. Rochester, N. Y., 3 Aug. 1836. He was graduated at Yale in 1857 and was Baptist clergyman at Haverhill, Mass. (1861-65) and Cleveland, Ohio (1865-72). He was president and professor of biblical theology at the Rochester Theological Seminary (1872-1912). He has written 'Systematic Theology'; 'Philosophy and Religion' and 'The Great Poets and Their Theology,' 'Christ in Creation and Ethical Monism,' 'Popular Lectures on the Books of the New Testament.'

STRONG, Caleb, American statesman: b. Northampton, Mass., 9 Jan. 1745: d. there, 7 Nov. 1819. He was graduated at Harvard College in 1764, studied law and was admitted to the bar in 1772. During the Revolution he was a member of the general court or legislature and of the Northampton committee of safety. For nearly 25 years after 1776 he was county attorney, in 1779 was a member of the State constitutional convention, and in 1780 of the State council, and several times represented his county in the State senate. In 1787 he was elected to the convention for framing a national constitution but was obliged by sickness in his family to return home before the completion of its labors; and in 1789 he was elected one of the first United States senators from Massachusetts, was re-elected in 1793 and resigned in 1796. From 1800 to 1807 he was governor of Massachusetts and again from 1812 to 1816. As a Federalist he was opposed to the war with England and he refused to comply with the President's order to call out the State militia on the plea that the governor alone had the right to decide whether or not the militia should be called out. Consult Alden Bradford's biography of him (1820).

STRONG, Frank, American educator: b. Venice, N. Y., 5 Aug. 1859. He was graduated at Yale in 1884 and was admitted to the bar in Rochester, N. Y., in 1886. Received degrees of A.M. and Ph.D. (Yale), 1893 and 1897, respectively. Received degree of LL.D., (Baker University, University of Oregon and Kansas State Agricultural College) 1910. He began the practice of law in Kansas City, Mo., but retired in 1888 to become principal of the high school at Saint Joseph, Mo. He was elected superintendent of schools at Lincoln, Neb., in 1892 and in 1897 was elected lecturer in history

in Yale University. In 1899 he was made president of the University of Oregon and in 1902 returned to Kansas where he was called to the chancellorship of the State University. His published works include 'The Government of the American People' (1891); 'Life of Benjamin Franklin' (1898); 'Cromwell's West Indian Expedition' (1899); 'A Forgotten Danger to the New England Colonies' (1898); 'Annual Reports to the Board of Regents, University of Oregon' (1900-01); 'Annual Reports to the Board of Regents, University of Kansas' (1902-12); 'The Problem of Higher Education in States that Maintain more than One College or University' (Transactions and Proceedings of the National Association of State Universities, 1908); 'Report of Educational Progress During the Year' (Proceedings of the National Education Association, July 1910); 'Control and Management of Athletics' (Transactions and Proceedings of the National Association of State Universities, 1913); 'Imagination in College' (*The Nation*, 1 March 1914); 'Economy of Time in Education' (Journal of Proceedings and Addresses, National Education Association, 1914); 'The Opportunity of American Universities' (*School and Society*, June 1915); and 'Present Activities and Accomplishments of Higher Education' (*School and Society*, October 1915). Served as member of the National Council of Education of the National Education Association; president of the section of higher education of the National Education Association; president, Kansas State Teachers Association; and president of the National Association of State universities. He is a member of the State Board of Education of the State of Kansas and a member of the Board of Education of the Northern Baptist Convention, United States. The University of Kansas enlarged and developed under his administration, adding to its schools and divisions the Summer Session, the School of Medicine, the School of Education, the Extension Division, the Division of State Service Work, the Biological Survey, the Engineering Experiment Station, etc.

STRONG, George Crockett, American soldier: b. Stockbridge, Vt., 16 Oct. 1832; d. New York, 30 July 1863. He was graduated from the United States Military Academy in 1857, and in the Battle of Bull Run was ordnance officer on General McDowell's staff. In 1862 he was in command of an expedition from Ship Island to Biloxi, Miss., and the next year participated in the operations against Charleston, and in the two attacks on Fort Wagner. In the last he fell mortally wounded. Fort De Kalb on the Potomac was renamed Fort Strong in his honor. Author 'Cadet Life at West Point' (1862).

STRONG, James, American biblical scholar: b. New York, 14 Aug. 1822; d. Round Lake, N. Y., 2 Aug. 1894. He was graduated (1844) at Wesleyan University, Middletown, Conn., then taught ancient languages at Troy Conference Academy, West Poughkeepsie, Vt., for two years, when he went to Flushing, L. I., where he continued his biblical studies, but undertook commercial enterprises, such as building the Flushing Railroad, of which he became president. He became professor of biblical literature (1858-61) and acting president

of Troy University. In 1868 he was made professor of exegetical theology at Drew Theological Seminary, Madison, N. J., but resigned on account of bad health 1893, and retired. He edited, in collaboration with Dr. McClintock 'The Cyclopædia of Biblical, Theological and Ecclesiastical Literature' (1867-85), continuing the work alone after the death of his co-worker. His 'Exhaustive Concordance of the Bible' (1894) was the outcome of the work of many years.

STRONG, Josiah, American clergyman: b. Naperville, Ill., 19 Jan. 1847; d. 28 April 1916. He was graduated at Western Reserve College in 1869, and studied at Lane Theological Seminary; was ordained in the Congregational Church, and held pastorates in Wyoming and Ohio; was secretary of the Evangelical Alliance for the United States in 1886-98. In the latter year he was made president of the League for Social Service. (Reorganized, 1902, as The American Institute of Social Service). President of Social Centre Association of America in 1911. His publications include 'Our Country' (1885); 'The New Era' (1893); 'The Twentieth Century City' (1898); 'Religious Movements for Social Betterments' (1900); 'Expansion' (1900); 'The Times and Young Men' (1901); 'The Next Great Awakening' (1902); 'The Challenge of the City' (1907); 'My Religion in Every Day Life' (1910); 'Our World; The New World-Life' (1913); 'Our World; The New World Religion' (1915). He was editor of 'Social Progress' (a year book) (1904-06); and edited *Gospel of the Kingdom*, a magazine, from 1908.

STRONG, Richard Pearson, American biologist: b. Fortress Monroe, Va., 18 March, 1872. He was graduated (1893) at Yale and received the M.D. diploma (1897) from Johns Hopkins. He was appointed (1899) president of the board for investigation of tropical diseases in the Philippines, and was director of the Government Biological Laboratory at Manila (1901-13), since which he has been professor of tropical medicine at Harvard. He was medical director of the International and American Red Cross Sanitary Commissions in Serbia in 1915, during the typhus epidemic.

STRONG, Sir Samuel Henry, Canadian jurist: b. Poole, Dorsetshire, England, 13 Aug. 1825; d. Ottawa, 21 Aug. 1909. He was taken to Canada in his 11th year by his father, who was appointed chaplain of the forces in Quebec and rector at Bytown (now Ottawa). He was educated at the Quebec High School, and under private tuition, taking later to law studies. In 1849 he was called to the Toronto bar, becoming partner with Sir Thomas W. Taylor (later chief justice of Manitoba), then with James David Edgar (later speaker of the Canadian House of Commons). Strong soon built up a high reputation, and was appointed (1856) on the commission for consolidating the statutes of Canada and Upper Canada. By 1869 he had risen to a position on the bench as a vice-chancellor of Ontario. He was member of the commission (1871) of enquiry into a union of the law and equity courts. He rose next (1874) to the Court of Error and

Appeals of Ontario, then (1875) to the Supreme Court of Canada as puisne judge, becoming (1892) successor to Sir W. J. Ritchie as chief justice. He resigned from this post in 1902 to become chief of the commission for consolidating the statutes of Canada. He was one of Canada's ablest jurists.

STRONG, Theodore, American mathematician: b. South Hadley, Mass., 26 July 1790; d. New Brunswick, N. J., 1 Feb. 1869. He was graduated at Yale University in 1812; became professor of natural philosophy and mathematics at Hamilton College in 1816-27; and held a similar chair at Rutgers College in 1827-61. In the realm of pure mathematics he was conceded to have no superior. After the ablest mathematicians of Europe had failed to solve the irreducible case of cubic equations left by Cardan, he discovered its solution by a direct method. His publications include 'Notes on the Parallelogram of Forces and on Virtual Velocities' (1864); 'On the Integration of Differential Equations of the First Order and Higher Degrees' (1864); 'A New Theory of the First Principles of the Differential Calculus' (1865); 'A Treatise on Elementary and Higher Algebra' (1859); 'A Treatise on the Differential and Integral Calculus' (1869).

STRONG, William, American jurist: b. Somers, Conn., 6 May 1808; d. 1905. He was graduated (1828) at Yale, and taught at Burlington, N. J., while studying law under Garret D. Wall. He was admitted to the bar at Reading, Pa., in 1832 and started practice there where he rapidly advanced to prominent civic positions. He was elected to Congress in 1846 as a Democrat, re-elected in 1848 and declined nomination in 1850 to return to private practice. In 1857 he became justice of the Supreme Court of Pennsylvania for a 15-year term, serving only 11, and attaining very high repute as a jurist. President Grant appointed him (1870) justice of the United States Supreme Court.

STRONG, William L., American merchant and mayor of New York: b. on a farm in Richmond County, Ohio, 22 March 1827; d. New York 1900. He began life as dry goods clerk in Wooster, Ohio, spent 10 years in trade in Mansfield, Ohio, then came to New York in 1853. He commenced here as salesman for L. G. Wilson and Company, a dry goods commission house, where he learned every detail of the business, when his firm failed in the panic of 1857. He entered his services with Farnham, Dale and Company's dry goods store till 1869, when he started the next year his own business of W. L. Strong and Company, succeeding to the trade of Farnham, Dale and Company. Branches in Boston and Philadelphia grew up with his great business success. Strong was a Republican and took a general interest in public matters, refusing office, however, till his party combining with reform Democrats got him to be candidate (1894) for mayor and he was elected. He was the last mayor before the founding of Greater New York, and the 91st mayor of New York.

STRONTIANITE, native strontium carbonate, a mineral usually found massive with a crudely fibrous and radiating structure. It

rarely occurs in perfectly developed, orthorhombic crystals simulating aragonite in form and twinning, spire-shaped, branching groups being the most common. It has good prismatic cleavage; is brittle, breaking with an uneven fracture; hardness 3.5 to 4; specific gravity 3.69; lustre vitreous; color usually yellowish-white, sometimes pale-greenish; streak white; transparent to translucent. Before the blowpipe it swells and sprouts, but fuses only on thin edges. It imparts to the flame the crimson color characteristic of strontium. Its name is due to its occurrence in Strontian, Scotland, but its most important locality is Hamm, Westphalia. It is found at Schoharie and elsewhere in New York. Celestite (SrSO_4) and strontianite are the minerals from which all of the strontium salts so valuable in sugar refining and in pyrotechnics are derived.

STROPHANTHUS, a genus of trees, shrubs or climbers, belonging to the family *Apocynaceæ*, and found in Asia and Africa, being chiefly tropical. The leaves are feather veined and opposite, and the cymose inflorescence is terminal. The flowers are handsome, ranging in color from white, through the yellows and reds, to purple. The calyces are glandular, the corollas funnel-shaped, with five lobes tapering into attenuated, long tails. The two carpeloid ovaries develop into capsular fruits having two diverging free follicles, which enclose the hairy seeds. A climbing species (*S. hispidus*) has seeds which are hairy and have a plumose tuft of silky hairs attached to their apexes, by a slender filament and which contain a bitter, poisonous glucoside called strophanthin. This poison contracts the voluntary muscles, and is so deadly that an elephant wounded by the spiked and strophanthus-poisoned beams, which are hung for the purpose in the runs of the huge beasts, is unable, it has been stated, to go more than 10 miles from the spot. Species of *Strophanthus*, especially *S. hispidus*, are powerful ingredients of those African arrow-poisons called in West Africa *inée*, *onaye* or poison of *Pahonias*, and in East Africa, *Kombé*; while still another near Somaliland is known as *wanika* poison. *Strophanthin* is a valuable cardiac stimulant, and a drug employed in heart disease, similar in its effects to *digitalis*, slowing the heart's action, and increasing its contractility and the tension of the arteries, but is more rapid and uncertain in its effects than the other drug. Several species are known in gardens and greenhouses, one, *S. petersianus*, being remarkable for its octopus-like twisted corolla lobes, colored red and yellow.

STROPHE, *strô'fê*, the name of one of the divisions of a Greek choral ode. It is a designation also often applied to the stanza in modern poetry. The singing of the strophes on the stage was accompanied with a motion or turn from right to left toward the images of the gods placed on the sides of the orchestra (in the ancient sense of this word); but the singing of the antistrophe, with a contrary motion, from the left to the right. In a poetical sense the strophe designates a union of rhythmical periods corresponding closely to a following combination.

STROSSMAYER, *strôs'mi-ër*, Joseph Georg, Hungarian bishop: b. Essek, Slavonia, 4 Feb. 1815; d. 1905. He was educated for the priesthood at the University of Budapest and at Vienna, and in 1849 was made bishop of the Croatian diocese of Diakovo. He was for many years the leader of the movement for the separate existence and self-government of Croatia, and was known as a zealous churchman. At the Vatican Council in 1870, he was the leader of the Opportunists, the party which opposed the declaration of the dogma of infallibility on the ground that the times were not ripe for the definition. But when the Council declared it to be a formal article of faith, he acquiesced and subscribed to it.

STROTHER, *stroth'ër*, David Hunter, American author and artist: b. Martinsburg, Va., 16 Sept. 1816; d. Charleston, W. Va., 8 March 1888. Before the outbreak of the Civil War his articles and illustrations of Southern life attracted wide attention, being especially noteworthy for their faithful presentation of Southern scenes and customs. He wrote under the nom de plume of "Porte Crayon," in 1852, a series of humorous papers in *Harper's Magazine* which attracted considerable attention owing to the fact that they presented a new and sympathetic view of the Southern States of the United States. He served as colonel in the Union army during the Civil War, and was consul-general to Mexico (1879-85). His writings were collected in book form and published under the names of 'The Blackwater Chronicle' (1853); 'Virginia Illustrated' (1857).

STROUDSBURG, *strowdz'bèrg*, Pa., borough, county-seat of Monroe County; on Broadhead Creek, and on the Delaware, Lackawanna and Western, and on the New York, Susquehanna and Western Railroads, about 25 miles north of Easton. It is in the Blue Ridge region, between the Delaware Water Gap and Mount Pocono. The climate, scenery, good water, and the good roads have made the place a favorite summer resort. There are public and private schools, and two national banks. Pop. about 5,000.

STROZZI, *strôt'sè*, the name of a wealthy and illustrious Florentine family, which came into prominence about the end of the 13th century. Palla, Filippo and Piero were the three most renowned members of this princely house, between 1432 and 1537, who were either exiled or lost their lives in the struggle for liberty against the power of the Medici family. The Strozzi family engaged in banking and became very wealthy and their wealth continued to steadily increase. With this increase of wealth grew their influence in Southern Italy which is said to have been upheld by over 80 Strozzi wealthy families. Their power was finally overthrown by Cosmo I di Medici in 1537. Various representatives of the Strozzi family still live in Florence where the titled head of the house has been, since 1722, the Prince of Forano.

STROZZI, Bernardo (IL PRETE GENOVESE, of IL CAPPUCINO), Italian painter: b. Genoa, 1581; d. Venice, 1644. He painted in the naturalistic style of Caravaggio, and produced

many frescoes and easel pictures in oils. They are all of a somewhat crude character, and fiery coloring, though the design is strong.

STRUCTURAL GEOLOGY, that branch of geology that treats of the architecture of the earth's crust. See **FAULT**; **FOLDS**; **MOUNTAINS**; **UNCONFORMIST**; also section on *Structural Geology* in article on **GEOLOGY**.

STRUCTURAL SHAPES. See **RAILS AND STRUCTURAL SHAPES, MANUFACTURE OF**.

STRUCTURAL STEEL. See **RAILS AND STRUCTURAL SHAPES, MANUFACTURE OF**; **STEEL**—**THE EVOLUTION OF STEEL MAKING PROCESSES**.

STRUENSEE, stroo'ën-zā, **Count Johann Friedrich von**, Danish statesman and philosopher; b. Saxony, 5 Aug. 1737; d. 28 April 1772. He studied medicine, and in 1768 was appointed physician to the king of Denmark. He soon became a favorite, and effected the dismissal of all those who were obstacles to his own ambitious plans. In 1770 he advised the king to abolish the council of state, and to establish the ancient royal power lost through the rise of the nobles to influence in 1660, a measure which roused the indignation of the Danish nobility. Struensee, by various means, gradually usurped the administration of all affairs in the name of the king, and caused himself to be created count. The king, Christian VII, a feeble-minded nonentity, was completely under his domination and that of the ambitious queen, who appears to have been in love with Struensee. Between them they appointed new ministers and proceeded to run the affairs of state. An alliance was formed with Sweden in opposition to the Russian influence that had previously been all powerful at the Danish court. Struensee appears to have been, under the guise of an autocrat, very much of a liberal. He mitigated the penal laws, greatly reduced the extent of serfdom and encouraged free industry and trade in opposition to the monopolies that had previously prevailed. This angered the clergy and the nobles who organized a conspiracy against him, and on 16 Jan. 1772, Struensee was seized, found guilty of criminal relations with the queen, convicted and executed.

STRUNSKY, strün'skī, **Simeon**, American author; b. Vitebsk, Russia, 23 July 1879. He was educated at Horace Mann High School, New York, and was graduated (1900) at Columbia. He was (1900-06) a department editor of the *New International Encyclopædia*, from 1906-13 he was editorial writer, becoming literary editor of the *New York Evening Post* (1913-14). He wrote 'The Patient Observer' (1911); 'Through the Outlooking Glass with Theodore Roosevelt' (1912), an amusing parody; 'Post-Impressions' (1914); 'Belshazzar Court, or Village Life in New York City' (1914); 'Post-Impressions' (1914). Most of his writings, including the above are in essay form, and are marked by good-humored satire and shrewd wit which make them entertaining reading.

STRUT, in architecture, a brace or support, either upright, horizontal or diagonal. The struts of a roof extend obliquely from a rafter to an upright post. Diagonal struts are frequently used in gates, doors and between joists.

STRUTHIONIDÆ, the ostriches and related ratite birds. See **OSTRICH**.

STRUTT, strüt, **Joseph**, English antiquary; b. Chelmsford, 27 Oct. 1749; d. London, 16 Oct. 1802. He was articled to W. W. Ryland, the engraver, studied engraving and painting and obtained the gold and silver medals of the Royal Academy. Later he devoted most of his time to research work in the British Museum. In 1773 he published his 'Regal and Ecclesiastical Antiquities from Edward the Confessor to Henry VIII' and shortly afterward his 'Horda Angel-Cynnan, or Manners, Customs, etc., of the English' (1774-76). His other works include a 'Chronicle of England' (1777-78); 'Biographical Dictionary of Engravers' (1785-86); 'Dresses and Habits of the People of England,' etc. (1796-99); and 'Sports and Pastimes of the People of England' (1801). He left some manuscripts, from which were afterward published his 'Queenhoo-Hall,' a romance, concluded by Sir Walter Scott; 'Ancient Times,' a drama; also 'The Test of Guilt, or Traits of Ancient Superstition,' a tale. His literary work and researches had considerable influence on Scott's 'Waverly' novels.

STRUVE, stroo'fē, **Friedrich Georg Wilhelm von**, Russian-German astronomer; b. Altona, 15 April 1793; d. 23 Nov. 1864. In 1813 he entered the Dorpat observatory, and was appointed director in 1817. On the completion of the Russian observatory at Pulkova, near Saint Petersburg, in 1839, he was nominated its director, and here he continued his researches on nebulae and double stars. From 1816 to 1819 he was engaged on the triangulation of Livonia, and from 1830 to 1845 he was connected with the measurement of the arc of the meridian in the Baltic provinces, which was afterward extended to the Arctic Ocean and the Danube. Among his published works are 'Observationes Dorpatenses' (1817-39); 'Catalogus Novus Stellarum Duplicium et Multiplicium' (1827); 'Stellarum Duplicium et Multiplicium Mensuræ Micrometricæ' (1837); 'Etudes d'astronomie stellaire' (1847); 'Stellarum Fixarum Imprimis Duplicium et Multiplicium Positiones Mediæ' (1852); 'Arc du Méridien de 25° 20' entre le Danube et la mer glaciale' (1857-60).

STRUVE, Otto Wilhelm von, Russian astronomer; b. 7 May 1819; d. 1905. He early studied at the Dorpat and Pulkova observatories, and on the death of his father, Friedrich-Georg Wilhelm von Struve (q.v.) he succeeded him as director of the great Pulkova observatory near Saint Petersburg. His work was given mostly to the observation of double stars, and continuing the organization and administration of the observatory founded by his father. He is credited with having discovered 500 binary stars in his examination of the northern heavens alone. He also discovered new principles in star measurement and phenomena and made interesting and valuable observations respecting the mass of Neptune, the dimensions of the ring of Saturn, solar velocity and corona extent. His published books, apart from the 14 volumes of 'Observations de Pulkova' which he edited, are to be found in technical journals devoted to his special field of work. He was the presiding

officer of the International Astrophotographic Congress at Paris in 1877. In 1890 he resigned the directorship at Pulkova and retired to Karlsruhe.

STRYCHNINE, strik'nin, (Latin *strychnos*, from Greek of same form) $C_{15}H_{21}N_2O_5$, an alkaloid existing in the seeds of the *Strychnos Nux-vomica*, Saint Ignatius bean, and the other species of *Strychnos*. The *Strychnos Nux-vomica* is a tree of medium size growing in the East Indies. It bears a pulpy fruit about the size of an orange, containing the large seeds that are the drug nux-vomica. These seeds are circular, about three quarters of an inch in diameter, an eighth of an inch thick, and very hard and horny. Rasped or filed they are used to kill cats, dogs, rats and vermin under the name of rats-bane or dog buttons. The active principle strychnine may be obtained by treating nux-vomica with alcohol containing a little sulphuric acid. This solution contains the strychnine as well as various coloring matters. From it the strychnine may be obtained in small white prismatic crystals, slightly soluble in water, giving it a bitter taste even in as dilute a solution as one part in 700,000. Strychnine is very poisonous, a small amount causing death with violent tetanic convulsions. It is, however, used extensively in very small doses in medicine, being valuable as a heart stimulant, and in cases of paralysis, nervous affections, dyspepsia, etc. It is a weak base forming salts with acids. The sulphuric acid salt or strychnia sulphate is used generally in place of the free alkaloid. Sulphuric acid and strychnine together form a colorless solution which is turned strongly violet by the addition of bichromate of potash. The purple rapidly changes into red and from that into yellow. See ALKALOIDS; TOXICOLOGY; BRUCINE.

STRYCHNOS, a genus of the family *Loganiaceae*, represented by trees, shrubs or vines which climb by stiff hooked tendrils, and are mostly tropical. The leaves are opposite, thin or coriaceous, and prominently three to five-nerved. The flowers are small and whitish, collected in dense axillary or terminal cymes, and are salver-shaped, with five valvate lobes. The ovary is usually two-celled and develops into an indehiscent, globose berry with a hard rind and pulpy interior enclosing the seeds. This pulp is sometimes innocuous, and is eaten by birds and men, but the seeds are generally violently poisonous. Those of the Indian *Strychnos potatorum*, when rubbed in a vessel of water, send all the impurities to the bottom, whence the name of clearing-nut tree. Its pulp is edible. While many of the species of *Strychnos* contain the poisonous alkaloid called strychnine, which is used in small quantities as a valuable medicine, most strychnine of commerce is obtained from the button-like, satiny seeds of *S. nux-vomica*, or nux-vomica tree (q.v.), or from those of *S. ignatii*, the Saint Ignatius bean. Strychnine is also the sole active principle in *S. tieute*, from Java, being extracted from the bark by boiling, and employed by the Javanese for poisoning their arrows. *S. toxifera*, a woody climber often three inches' thick, with hooked tendrils, and covered with dark-brown hairs, is found in South America, and, with other species, is supposed to be the source of

the arrow poison called woorali or *curare*. This substance is black-brown, like an extract, or firmer, brittle and friable; it is used somewhat in medicine as a nervous sedative, and in physiological experiments. The South American Indians put it on arrows, chiefly on those shot from blow-guns, and use it for hunting, since the game is wholesome after being poisoned. Curare acts by paralyzing the terminals of the motor nerves, and causes death instantly when mixed with the blood, by paralyzing the muscles of the chest, and so suffocating the victim. The bark of *S. nux-vomica* was at one time introduced as a substitute for Angostura bark, with such deadly effect that the use of the latter was discontinued for a while. In Brazil, however, the cortex of *S. pseudo-quina* has been used as a febrifuge. *S. colubrina* furnishes the snakewood (q.v.).

STRYKER, striker, Melancthon Woolsey, American college president: b. Vernon, N. Y., 7 Jan. 1851. He was graduated from Hamilton College, New York, in 1872 and from Auburn Theological Seminary in 1876. He held pastorates in the Presbyterian Church, 1876-83, in the Congregational Church, 1883-85, and again in the Presbyterian Church, 1885-92. From 1892-1917 he was president of Hamilton College. A student of hymnology he published, among others, the following hymns and poems; 'Song of Miriam' (1888); 'Church Song' hymnal (1889); 'Lattermath Verse' (1896); 'College Hymnal' (1897); 'Faculae Annorum' (1917); and is author of 'Well by the Gate,' sermons (1903); 'Baccalaureate Sermons' (1905); 'English Bible Versions and Origins' (1915); 'Three Addresses on Lincoln' (1917).

STRYKER, William Scudder, American historian: b. Trenton, N. J., 6 June 1838; d. there, 29 Oct. 1900. He was graduated from Princeton in 1858, enlisted in the Union army and served on General Gillmore's staff in South Carolina; was returned north on account of ill-health, resigning his commission in 1866. He was adjutant-general of New Jersey from 1867 until his death. He published a 'Roster of Jerseymen in the Revolutionary War' (1872); a 'Roster of New Jersey Volunteers in the Civil War' (1876); and 'The Battles of Trenton and Princeton' (1898).

STUART, the name of a royal family of Scotland and England, also written Stewart and, less frequently, Steuart. The name is derived from the important office of steward of the royal household of Scotland. The founder of the house seems to have been a Norman baron named Alan (the son of Flaad) a follower of William the Conqueror, who obtained the lands and castle of Oswestry, in Shropshire. His second son, Walter, entered the service of David I of Scotland, by whom he was appointed dapifer, that is, meatbearer, or steward of the royal household. The steward obtained from David the lands of Renfrew, Paisley, Pollock, Cathcart, and others in that district; he founded the abbey of Paisley in 1160; and died in 1177. His grandson Walter held, in addition to the office of steward, that of Justiciary of Scotland. He died in 1246. His eldest son, Alexander, the 4th steward, seized the islands of Bute and Arran, in the right of his wife Jean, heiress of James, lord of Bute. This led to the expedition of Hacon of Norway,

and the battle of Largs (1263), in which the steward is said to have commanded the right wing of the Scots, greatly contributing to the defeat of the Norwegians. Alexander had two sons, JAMES, the 5th steward, and JOHN, known in history as that Sir John Steward of Bonkyl, or Bonkill, who was killed at the battle of Falkirk (22 July 1298). The eldest of Sir John's sons, ALEXANDER, was the ancestor of the Stewart earls of Angus; the 2d ALAN, of the Stewart earls and dukes of Lennox; the 3d, Walter, of the earls of Galloway; the 4th, of the earls of Athol, Buchan and Traquair and the Lords Lorn and Innermeath. James, the elder brother of Sir John, succeeded as 5th steward in 1283. Three years later, on the death of Alexander III he was chosen one of the regents of the kingdom. He fought bravely under Wallace for some time, but submitted to Edward I in 1297. In spite of the most solemn oaths which the English king obliged him to take, he died in the service of Bruce in 1309. His son, WALTER, the 6th steward, had an important command in the Setch army at Bannockburn. Some time after, King Robert bestowed the hand of his daughter Marjory upon him, a union which brought the crown of Scotland, and eventually that of Great Britain into his family. Walter was succeeded by his son, ROBERT, the 7th steward. During the long and disastrous reign of David II, the steward distinguished himself by his patriotic exertions for the defense of Scotland, defeating the intrigues of that prince and Edward III to seat Lionel, Duke of Clarence, on the Scottish throne. On the death of David, without issue, the steward peacefully succeeded to the crown as Robert II in 1371, and died in 1390. From this time to the death of James V in 1542 the crown of Scotland remained in the direct male line of Stuarts, passing in unbroken succession from father to son. James V left a daughter Mary who succeeded to the throne. Her son, James VI of Scotland, succeeded to the English throne on the death of Elizabeth, tracing his claim through his great-grandmother Margaret, a daughter of Henry VII of England. The Stuarts were driven from England in the person of James II in 1688. (See for the history of the royal line, ROBERT II and III; JAMES I, II, III, IV, V; MARY STUART; JAMES I (of England); CHARLES I and II; JAMES II; WILLIAM and MARY, and ANNE). James II of England was twice married, first to Anne Hyde, daughter of Lord Clarendon, by whom he had Mary, queen of William III, and Anne, both of whom died leaving no issue. His second wife, Mary of Modena, gave birth, on the eve of the revolution, to James Edward Francis, Prince of Wales, commonly called the Old Pretender, or the Chevalier St. George. The legitimacy of this prince was long doubted; a great majority of the nation was convinced that the queen had never given birth to a child; but that there was no imposture is now a matter of historical belief. On the outbreak of the revolution, the queen and her infant son took refuge in France, and on the death of the ex-king, Louis recognized the child as king of England by the title of James III. In 1715 an unsuccessful attempt was made to seat him on the throne of his ancestors by force of arms. James Edward, who had landed in Scotland after his cause had been irretrievably lost, suc-

ceeded in making his escape. France, however, no longer offered him an asylum, as the Regent Orleans wished to stand well with the English government, and the Pretender went to Rome, where he lived in obscurity until his death in 1766. In 1720 he married the Princess Maria Clementina Sobieski, granddaughter of John Sobieski (q.v.), king of Poland, one of the wealthiest heiresses in Europe, by whom he had two sons, Charles Edward Louis Casimir (see CHARLES EDWARD STUART), and Henry Benedict Maria Clement, born at Rome in 1725. In 1745, when the last effort was made for the restoration of his family, Henry Benedict assumed the command of the troops assembled at Dunkirk to aid the operations of his brother in Britain, but the news of the battle of Culloden prevented the embarkation of this armament, and Prince Henry returned to Rome. He took holy orders, and in 1747 was raised by Benedict XIV to the purple. On the death of his brother in 1788, he assumed the barren title of Henry IX, king of England. When the French conquered Italy he was obliged to flee to Venice, where, stripped of his bishoprics and rich church livings, he lived in great poverty until George III settled on him a pension of £4,000, which he enjoyed till his death in 1807. Next to the children of James II in representation of the royal Stuart family, come the descendants of Henrietta Maria, daughter of Charles I, and wife of Philippe, duke of Orleans, brother of Louis XIV of France. This princess gave birth to two daughters, Mary, who married Charles II of Spain, but had no issue, and Anna Maria, wife of Victor Amadeus, king of Sardinia.

The present representative of this line is Archduchess Maria Theresa of Austria-Este of the branch of Modena, wife of ex-King Ludwig III of Bavaria, eldest son of the regent Luitpold (d. 12 Dec. 1912). The present royal family of Great Britain trace their descent through Sophia, electress of Hanover, granddaughter of James I, by her mother Elizabeth, electress palatine, and queen of Bohemia. George V derives his descent from the electress Sophia through George I, George II, Frederick, Prince of Wales, George III, Edward, Duke of Kent, Queen Victoria and Edward VII. Consult Cowan, S., 'The Royal House of Stuart from its Origin to the Accession of the House of Hanover' (2 vols., London 1908).

STUART, Arabella, commonly called the **LADY ARABELLA**: b. Chatsworth, 1575; d. London, 27 Sept. 1615. This unhappy and innocent victim of jealousy and state policy was the only child of Charles Stuart, Earl of Lennox, younger brother to Henry Lord Darnley, the husband of Mary Queen of Scots. She was, therefore, cousin-german to James I, to whom, previously to his having issue, she was next in the line of succession to the crown of England, being the great-great-granddaughter of Henry VII, whose daughter Margaret, having been first married to James IV of Scotland, became by a second marriage the mother of Margaret Douglas, mother of Darnley, and Charles Stuart, Earl of Lennox. She received an excellent education. Her proximity to the throne was the source of her misfortunes. Elizabeth, for some time before her decease, held the Lady Arabella under restraint, and refused the

request of the king of Scotland to give her in marriage to the Duke of Lennox, his kinsman, with a view to remove her from England. The Pope had likewise formed the design of raising her to the English throne, by espousing her to the Duke of Savoy; which project is said to have been listened to by Henry IV of France, from a wish to prevent the union of England and Scotland. The detection of a plot of some English nobles to set aside James in favor of Arabella Stuart, of which she was altogether innocent, ultimately proved her destruction; for although left at liberty for the present, when it was some time after (in 1610) discovered that she was secretly married to William Seymour, son of Lord Beauchamp and grandson of the Earl of Hertford, both husband and wife were placed in confinement, the husband being committed to the Tower. At the end of a year they both contrived to escape at the same time, but the unhappy lady was retaken. She was then herself committed to the Tower, the remainder of her life was spent in close confinement, which finally deprived her of her reason. Consult Bradley, E. T., 'Life and Letters of Lady Arabella Stuart' (London 1889).

STUART, Charles Edward Louis Philip Casimir, of Scotland: b. Rome, 31 Dec. 1720; d. there, 31 Jan. 1788. He was a son of James Francis Edward Stuart, and was known variously as the "Young Pretender," the "Young Chevalier," and "Bonny Prince Charlie." He first saw service at the siege of Gaeta (1834); fought bravely at Dettingen (1743); and next year repaired to France to head Marshal Saxe's projected invasion of England. Sailing from Nantes, he landed with seven followers at Eriska in the Hebrides on 2 Aug. 1745, and on the 19th raised his father's standard at Glenfinnan. The clansmen flocked in; on 17 September Edinburgh surrendered, though the castle still held out; and Charles held court at Holyrood, the palace of his ancestors. There followed the victory over Sir John Cope at Prestonpans, the march upon London with 6,500 men, the fatal turning at Derby (6 December), the victory over Hawley at Falkirk (17 Jan. 1746), the crushing defeat by the Duke of Cumberland at Culloden (16 April), and Charles' five months' hidings and wanderings. The peace of Aix-la-Chapelle (1748) caused his forcible expulsion from France, and thereafter he lived successively at Avignon, Liège, Basel, Florence and Rome.

STUART, Charles Macaulay, American theologian: b. Glasgow, Scotland, 20 Aug. 1853. He was graduated (1880) at Kalamazoo College and took the A.M. degree (1883) at Garrett Biblical Institute and Northwestern University (1887). He was pastor at River Forest, Ill. (1880-83), at Fort Saint Church, Detroit (1883-85), becoming associate editor *Michigan Christian Advocate* (1885-86) and filling the same position on the *Northwestern Christian Advocate* (1886-96). From 1896-1909 he was professor of sacred rhetoric at Garrett Biblical Institute and was appointed editor *Northwestern Christian Advocate*, 1909-11. He became president of Garrett Biblical Institute in 1911. He has written 'Gospel Singers and Their Songs' (1891); 'Vision of Christ in the Poets' (1896); 'Story of the Masterpieces' (1897). He also edited the 'Methodist Hymnal' (1905);

'In Memoriam, Charles J. Little' (1912); 'The Manifold Message of the Gospel' (1913).

STUART, Elizabeth, daughter of James I of England. See ELIZABETH STUART.

STUART, Gilbert, American painter: b. Narragansett, R. I., 3 Dec. 1755; d. Boston, 27 July 1828. He was a portrait painter and began at the age of 13. In 1775 he paid his second visit to England where Benjamin West recognized his talent, took him into his home and gave him instruction in art. Eventually obtaining much favor and distinction in London he painted portraits of George III, George IV while prince of Wales, Mrs. Siddons, Sir Joshua Reynolds, Benjamin West, and at Paris had Louis XVI as sitter. His great ambition, however, was to practise his art in his own country and he returned to the United States 1792 and opened a studio first in New York; subsequently in Philadelphia, where he painted Washington in 1795. This was the first of a series of portraits of the "Father of his Country" by Stuart. There are still extant six half-face portraits from the same sitting, painted from the right. The famous "Athenæum portrait," now in the Boston Museum, was produced about 1796 and takes the left half face of the sitter. Somewhere about the same time he painted a full-length portrait of Washington for the Marquis of Lansdowne. Nearly 40 copies made by him from the original of various sittings are now in existence. In the Metropolitan Museum of Art, New York, Stuart is represented by six pictures, namely 'Washington' (two portraits); 'John Jay'; 'Captain Henry Rice'; 'Mr. David Sears'; 'Commodore Isaac Hull.' He also painted the first five Presidents of the United States; Edward Everett, Jacob Astor; Judge Story; W. E. Channing; Josiah and Edmund Quincy and O. H. Perry. The characteristics of Stuart's portraits are fine coloring and life-like expression. Though he has been charged with incorrectness of drawing, he ranks with some of the best portrait painters of the English-American school. Consult Mason, 'Life and Works of Gilbert Stuart' (1879); Isham, S., 'History of American Painting' (New York 1915).

STUART, Henry Benedict Maria Clement, Duke of York, cardinal and bishop of Frascati: b. Rome, 5 March 1725; d. Paris, 1799. He was a son of James Francis Edward Stuart. In 1747 received a cardinal's hat from Benedict XIV. Clement XIII consecrated him bishop of Corinth, and subsequently appointed him to the suburban see of Frascati. He enjoyed, through the favor of the French court, the revenues of two rich abbeys, as well as a Spanish pension; and the liberal charity with which he dispensed his income endeared him to his flock. On his brother's death in 1788 he caused a medal to be struck, bearing the Latin legend, "Henry IX, king of England, by the grace of God, but not by the will of men." The French Revolution stripped him of his fortune.

STUART, James, Earl of Murray; regent of Scotland: b. 1533; d. 21 Jan. 1570. He was the natural son of James V by Margaret, daughter of Lord Erskine. At five years of age his father made him prior of Saint Andrews, and he was long known by that title. He be-

came a warm supporter of the Reformers, and was chosen a member of the council, and one of the lords of the articles. On the return of Mary to Scotland as queen, Murray became her chief adviser, and was created first, Earl of Mar, and then Earl of Murray. He was opposed to the queen's marriage with Darnley, and has been accused of implication in the murder of the latter. He remained out of Scotland for some months in 1567, only returning on the accession of James VI. He saw his sister a captive in Lochleven Castle, and was soon after named regent. Mary having escaped and taken arms, he encountered and defeated her at Langside, in 1568. He was assassinated at Linlithgow.

STUART, James, English antiquary and architect: b. London, 1713; d. 2 Feb. 1788. In his early days he devoted himself to the painting of fans, a profession which gave some room for the cultivation of a genuine artistic talent. In 1742 he went to Rome and engaged in the study of its architectural monuments. When in 1750 he accompanied Nicholas Revett to Greece, he found leisure and opportunity for completing his architectural knowledge. After traveling from point to point of antiquarian interest he finally settled in Athens for nearly three years and amassed a great body of material in the way of sketches and antiquarian notes. He returned to England in 1755 where he found his services much sought after as an architect, but his principal employment was the completion of his *magnum opus*, 'The Antiquities of Athens' in three volumes, only one of which was published before his death.

STUART, Sir James, Canadian jurist and statesman: b. Fort Hunter (now in New York State), 4 March 1780; d. Quebec, 14 July 1853. He was educated at Schenectady, then at King's College, Windsor, Nova Scotia. He next studied law in a prothonotary's office at Montreal, then (1798) becoming a pupil of Jonathan Sewell at Quebec. In 1800 he was appointed assistant secretary to the government of Lower Canada and was called to the bar in 1801 and made solicitor-general for the province. He entered the House of Assembly (1808) as member for Montreal. In consequence of disagreements he had to resign the solicitor-generalship and joined the opposition. He was sent to England by the advocates of the union of Upper and Lower Canada and (1825), was appointed attorney-general for Lower Canada and was elected the same year to the Assembly. Beaten in the following election (1828), he was next (1831) impeached by the House of Assembly and was suspended from office by Lord Aylmer, the claims against him being corruption in elections and improper use of office. The litigation was kept open by him in his defense both in Canada and England, but (1834) he resumed his private practice and his great success was proof of the public's confidence in him. In 1838 he was appointed chief justice of Lower Canada. He at once re-entered the political field, assisted Lord Sydenham with his advice and drew up many legal ordinances and other work in framing the union. He was created baron in 1841 for his services and on the union of the two Canadas became chief justice of Lower Canada.

STUART, James Ewell Brown, American soldier: b. Patrick County, Va., 6 Feb. 1833; d. Richmond, Va., 12 May 1864. He was descended on his father's side from ancestors distinguished during the colonial and Revolutionary periods, in the War of 1812, and in civil life in Illinois, Missouri and Virginia. On his mother's side he was a descendant of the Letcher family of Virginia. After a course at Emory and Henry College, in Virginia, he entered the National Military Academy at West Point, N. Y., and upon his graduation in 1854 was commissioned third lieutenant and in October of the same year was promoted to the rank of second lieutenant. After serving with the mounted riflemen against the Apaches in Texas he was transferred to the First Cavalry, then stationed at Fort Leavenworth. In December 1855 he was promoted first lieutenant, about a month after his marriage at Fort Riley to the daughter of Col. Philip St. George Cooke. He accompanied Col. Robert E. Lee as aide in the attack upon John Brown and his raiders at Harper's Ferry, where he read to Brown the summons to surrender. In April 1861 he received from the United States government the commission of captain; but he had decided to go with Virginia, and as soon as his resignation was accepted (7 May 1861) tendered his services to his native State, and was three days later commissioned lieutenant-colonel of Virginia infantry. Reporting to "Stonewall" Jackson at Harper's Ferry, he was promoted colonel 16 July 1861, and at the head of 350 cavalymen began his brilliant career. On outpost duty he was ever vigilant and wary, and of his service at the first battle of Manassas (Bull Run), where he made a dashing charge, General Early wrote that "Stuart did as much toward saving the battle as any subordinate who participated in it." After the victory had been won he pursued the Federals 12 miles. Subsequently he held the heights in sight of Washington with headquarters on Munson's Hill. In front of this position and at Dranesville he had combats with the Federals. On 24 Sept. 1861 he was commissioned brigadier-general. In the spring of 1862 he covered the retreat from Yorktown and opened the battle at Williamsburg (q.v.). For his daring raid around the army of General McCellan, just before the Seven Days' Battle, (q.v.), Stuart won the applause and hearty admiration of both friend and foe, and on 25 July 1862 he was commissioned major-general. He won additional fame by his raid around Pope's army, in which he captured that general's headquarters and a part of his staff at Catlett's Station by his raid in conjunction with General Trimble upon the Federal depot of supplies at Manassas, his services in screening the movement of Lee's army into Maryland, the brilliant fighting of his troopers at the passes of South Mountain, and by the skill with which he managed his horse-artillery on the Confederate left at Sharpsburg (Antietam), where with these hard fighters he powerfully assisted in the repulse of Sumner's gallant charge.

In October after the battle of Sharpsburg Stuart led his bold horsemen to Chambersburg, Pa., and on his return, thwarting every effort of the Federal cavalry to intercept him, passed between McClellan's army and Wash-

ington, and with little loss recrossed the Potomac into Virginia. This expedition caused great demoralization in the Federal cavalry, and by delaying McClellan's advance gave to the Army of Northern Virginia several weeks for rest and preparation against a new invasion.

After the mortal wounding of "Stonewall" Jackson and the disabling of A. P. Hill on 2 May at Chancellorsville, Stuart took command of Jackson's corps and by his audacious attack upon greatly superior numbers completed the work so brilliantly begun by Jackson. When Lee began his movement into Pennsylvania, Stuart, after defeating the Federal cavalry at Fleetwood, or Brandy Station (q.v.), passed again between the Federal army and Washington with orders to meet Early at York. Marching almost without rest for eight days and nights, the last three with almost constant fighting, he joined Lee's army at Gettysburg (q.v.), bringing with him a large train of captured Federal supplies. On the third day of the battle he made a fierce attack upon the cavalry on the Federal right, and at Williamsport, on the retreat, came up in time to drive off the heavy odds of Federals, who were making a desperate fight to capture the Confederate train so bravely defended by General Imboden. On 5 May 1864 he guided the movement of A. P. Hill's corps against Grant's advance, on the 7th gave notice to Lee of Grant's flank march to Spottsylvania Court House and, throwing his cavalry in front of the Federals, delayed them until the Confederate infantry could be thrown across their path. When Sheridan attempted to make a sudden dash into Richmond, Stuart with a part of the cavalry barred his way at Yellow Tavern (q.v.), and saved the Confederate capital. But he received a mortal wound, of which he died next day (12 May 1864) in Richmond. John Esten Cooke has written thus of his last moments: "As his life had been one of earnest devotion to the cause in which he believed, so his last hours were tranquil, his confidence in the mercy of heaven unflinching. When he was asked how he felt, he said, 'Easy but willing to die, if God and my country think I have done my duty.' His last words were: 'I am going fast now; I am resigned. God's will be done.' As he uttered these words he expired."

In every battle Stuart's black plume had waved in the advance. In every arm of the service he had won the highest honors. Gay and rollicking in camp, merry on the march, often calling upon Sweeny to ride by his side and thrum upon the banjo an accompaniment to his merry songs, he was always fully awake to the demands of duty and equal to any emergency. See STUART'S RAID TO CHAMBERSBURG; STUART'S RIDE AROUND THE ARMY OF THE POTOMAC ON THE CHICKAHOMINY. Consult McClellan, H. B., 'The Campaigns of Stuart's Cavalry' (1885).

JOSEPH T. DERRY,
Author of 'History of Georgia.'

STUART, James Francis Edward, the Pretender, of Scotland: b. Saint James Palace, 10 June 1688; d. Rome, 1 Jan. 1766. He was a son of James, regent, and Mary of Modena. At six months he was conveyed by his fugitive mother to Saint Germain, where his boyhood was passed, and where, on his father's death in 1701, he was proclaimed his successor. In

an attempt, in March 1707, to make a descent upon Scotland, the young "Chevalier de Saint George," as he was styled by his adherents, showed some gallantry, but was not suffered to land; and after his return he served with the French in the Low Countries, at Malplaquet receiving a sword-thrust in the arm. But in Mar's ill-conducted rebellion (see JACOBITES) he showed himself heavy, spiritless, even tearful, when, too late in the day, he landed at Peterhead (22 Dec. 1715), and sneaked away six weeks afterward from Montrose. France was now closed to him by the treaty of Utrecht, and almost all the rest of his fainéant, dissolute, prayerful life was passed at Rome. In 1719 he married Maria Clementina Sobieski, granddaughter of John Sobieski, king of Poland. Charles Edward, his son, was the Young Pretender.

STUART, John McDouall, Australian explorer: b. Dysart, Fifeshire, Scotland, 7 Sept. 1818; d. London, 5 June 1866. He was educated in Edinburgh, where he engaged in business for some time. In 1838 he went to Australia and accompanied Sturt's expedition into the interior, 1844-46. In 1858 he started a series of six expeditions in search of a path across the continent of Australia. The first had no noteworthy result; but on the second, in 1859, he explored much of the country about Lake Torrens. In 1860 he penetrated to the centre of Australia and discovered Mount Stuart; and at last, in 1862, his sixth expedition, succeeded in crossing Australia near the centre of the continent, from south to north and back again. For this achievement Stuart was granted £2,000 and 1,000 square miles of land by the Australian government. He wrote 'Explorations in Australia,' edited and published by W. Hardman (1864).

STUART, Moses, American biblical scholar and theological teacher: b. Wilton, Conn., 26 March 1780; d. Andover, Mass., 4 Jan. 1852. He was graduated at Yale in 1799; studied law, and was admitted to the bar in 1802; was tutor at Yale for two years; studied theology with President Dwight; in 1806 became minister of the First Church (Congregational) in New Haven; and in 1809 entered upon his life-work as professor of sacred literature in the Andover (Mass.) Theological Seminary, a position which he held until 1848. In the encouragement and direction of biblical study during this period his influence was widely felt, as it also was in the theological discussions of the time, which enlisted many able controversialists of various schools. More than 1,500 ministers were the recipients of his teachings at the seminary, and many pens and pulpits aided in the propagation of his views. Besides textbooks and commentaries relating to the biblical writings, he published 'Elements of Interpretation,' from the Latin of Ernesti (1822); 'Philological View of Modern Doctrines of Geology' (1836); 'Hints on the Prophecies' (1842); 'Critical History and Defense of the Old Testament Canon' (1845), and a volume of 'Exegetical Essays' (1867).

STUART, Ruth McEnery, American author: b. Avoyelles, La., 1856; d. 4 May 1917. She was educated in New Orleans until 1865; removed to New York in 1885. Her writings include 'A Golden Wedding, and Other Tales'

STUCCO, in *architecture*, a composition of white marble pulverized and mixed with plaster of lime, which, being sifted and wrought up with water, is used like common plaster. Architectural and sculptural ornaments, such as fruits, flowers, garlands, festoons, etc., are made of it. In the interior of buildings stucco work is generally applied to the ceilings of apartments, the moldings, etc. In some countries a stucco of common mortar and of plaster is applied to the outside of houses, and is extremely durable.

STUCK, Franz, KNIGHT VON, German painter: b. Tettenweis, Lower Bavaria, 23 Feb. 1863. He received his early art training in the academy at Munich under Lindenschmit and exhibited striking and original talent by his fantastic and grotesque designs, many of them furnished as illustrations to the *Fliegende Blätter*, as book covers, vignettes for programs, etc. In 1889 he made his début as a painter in oils with 'The Seraph at the Gate of Paradise'; and numerous other Biblical, mythological and allegorical works followed. His chief works are 'Lucifer'; 'The Expulsion from Paradise'; a 'Pietà'; 'The Crucifixion'; 'Sin' (1893); 'War' (1894), both in the Munich Pinakothek; 'The Sphinx' (1895), now in Budapest; 'Evil Conscience' (1896); 'Procession of Bacchantes' (1897); 'Pan' (1908); 'Innocentia' (1909). Among his most successful portraits is one of Fritz Scheff. He has also produced several statuettes and bronze figures, including 'The Faun' (in the Berlin National Gallery), and is professor royal in the Munich Academy. He is regarded now as one of the greatest figures in modern German art, although at first his work was scorned and derided. Consult Bierbaum, O. J., 'Stuck' (in 'Künstler-Monographien,' Vol. XLII, Bielefeld 1899); Singer, H. W., 'Franz Stuck: Zeichnungen' (Leipzig 1912); Hanfstängl's reproductions (Munich 1902).

STUCK, Hudson, American clergyman: b. England, 11 Nov. 1863. He was graduated (1892) at the Theological Department, University of the South, Sewanee, Tenn. He became (1892) deacon and priest of the Protestant Episcopal Church and rector (1892-94) at Grace Church, Cuero, Tex., dean (1894-1904), Saint Matthew's Cathedral, Dallas. Since 1904 he has been archdeacon of the Yukon. He has written 'Ascent of Denali' (Mount McKinley) (1914); 'Ten Thousand Miles with a Dog Sled' (1914); 'Voyages on the Yukon and its Tributaries' (1917). He was in the first party of three climbers to reach the summit of Denali Peak, in 1913, about 20,500 feet high; an account of the ascent is the subject of one of the above-mentioned works.

STUCLEY, stūk'li, or **STUKELY**, Thomas, English adventurer: b. about 1525. d. Alcazar, 4 Aug. 1578. He was sent to England (1552) recommended by Henry II of France, to whose notice he had been brought through his military talents. Instead of obtaining the secret information he was sent for that would assist the French to land on English shores after a projected capture of Calais, he disclosed the French royal plot. Instead of being rewarded for his information he was thrown into the "Tower" and the Duke of Northumberland betrayed him in turn to the

French king. Escaping from prison he entered service under Emperor Charles V and the Duke of Savoy. He was actively present at the victory of Saint Quentin (1557), after which he went on a privateering expedition, Queen Elizabeth providing one of his fleet of six ships (1563). His voyage was a series of robbery from ships of every nationality. After two years of piracy the remonstrances of other nations caused Elizabeth to arrest him. Upon being pardoned he went to Ireland where he is alleged to have started further plotting but the queen squelched his ambitious schemes. He had been in correspondence with Philip II of Spain, accepting a pension from him. Suspicion of his treason came up in court and he fled to Spain (1570) where he again plotted against England. He visited Paris and the papal court, then joined in an expedition against Morocco backed by Portugal but was killed in the battle of Alcazar (1578). The story of Stukely's career was very popular in England as he was said to have been an illegitimate son of Henry VIII, king of England. A play entitled 'The Battle of Alcazar . . . with the Death of Captain Stukely' was printed by E. Alde in 1594. Later 'The famous History of the Life and Death of Captain Stukely was printed (1605), Simpson's 'School of Shakespeare' (1878, Vol. I) gives a detailed account of Stukely's career based on state papers.

STUDENT LIFE AND CUSTOMS.

Student life and customs have varied so much in various ages and countries, and have differed so greatly according to the school, elementary, secondary or college, in which the students are, that it is necessary to divide and subdivide the subject for effective treatment.

Consideration must be given to ancient, mediæval and modern times; particular countries in those ages; the grade of institution, whether elementary, secondary or collegiate, in each country; and the life of the student both inside and outside of the classroom or academic precincts.

We lack sufficient evidence to make many statements about student life in ancient times. That which we do know has almost entirely to do with the teaching in the classroom (see EDUCATION, HISTORY OF). Of the life of the student there, the connection between flogging and learning was the feature—"he that is not flogged, can not be taught."

With the Greeks much of the instruction given to the young was in the nature of that which we should call supervised sports. This being the case student life for the young was happy and entertaining. The Greek boy played ball, flew kites and rolled marbles, and engaged in similar recreations.

As he grew older, if he were not apprenticed to a trade, he attended the gymnasia, which were open air exercising grounds. Here he got instruction in running, wrestling, boxing, spear throwing, jumping and hurling the discus. Horse-back riding and chariot driving were also a part of his instruction. Oratory and music came nearer than other subjects to being academic work in our sense of the word, but to-day even these subjects are likely to be more thought of in the nature of student life rather than a part of the instructional work in our educational institutions.

The Roman schools partook a little more of the nature of actual classrooms, though in most cases they were merely a sort of pergola. School-boy life was enlivened with floggings, as with the Greeks, but seemingly more systematic classroom work was done by the Romans. The latter did not give the time to formal instruction in sports that the Greeks gave, so that to the Roman boy and youth his amusements were much more his own. Marbles, blindman's buff, hide and seek and other games of childhood were played. Riding, swimming and wrestling were, however, a regular part of the instruction, and the Roman youth entered them with a seriousness that made them less a part of the lighter side of life. With the Romans, therefore, the sports of student life tended to fall into the class of the professionals.

For some centuries after the gradual decline of the Roman civilization until the beginning of those schools which grew up in connection with the Christian churches there is little evidence of any kind of school life. When the church and monastic schools did begin to come into existence, they were looked upon as places where in general boys were to be prepared for the service of the Church. Even those who were not to be so prepared were given the same kind of training. In view of the severity of the ideal of preparation for the Church the school life of the boy both during the hours of actual instruction and outside of such hours was one of constant task and supervision. Almost every sport to which a boy of the time might turn was prohibited under the severest penalties. Flogging, even of young men of 18, was common. Unlike the schools of the Greeks and the Romans, those in the Middle Ages were frequently of the kind to which boys went to live during their period of school life. The only holidays he had were those of the Church.

In spite of the extreme repression of all youthful inclinations, the boys committed numerous offenses in the schoolrooms and in chapel. Some, when they got a chance to get away from the strict supervision of the teacher, indulged in all kinds of prohibited sports, such as cock-fighting, gambling and fist fighting.

It was in the mediæval universities that we first hear of those student groups which gave color to a real student life such as we know it. The freshman was then, as until recently in our own colleges and universities, the particular object of attack on the part of those who had been in the institution longer than he. He was likely to be waylaid and thoroughly pummeled before arrival. In Germany and France he was put through an initiation bordering on the grotesque, horrible and cruel—far worse than the modern initiation to any of our secret societies. If he passed through such ordeals and succeeded in getting registered with a master or in a college, his life in the classroom and out of it was marked by turbulence and hardship. A master who delivered his lecture too rapidly was interrupted with all kinds of noises. The lecture-rooms were wholly unheated in winter and the windows unglazed. The floors were covered with straw on which the student sat. The rooms in which the students lodged were equally uncomfortable and the sanitary arrangements negligible. The ecclesiastical gowns which they were required to

wear afforded them scant protection against the cold, unless they were fortunate enough to be able to buy furs. Many of the students were well-to-do and others extremely poor. In whichever condition they found themselves letters to their parents which have come down to us give evidence of that almost chronic appeal of all students in all ages for more money. The poorer students frequently begged and were sometimes officially licensed to do so.

So many of their natural inclinations for the amusements and sports of youth were repressed by strict prohibitions that the natural consequences followed. Not having any outlet for their youthful spirits they indulged in riotous conduct. Brawls amongst the individual students and those of different national groups were frequent, and occasionally a whole group of them would get into conflict with the townsfolk, so that "Town and Gown" fights became infamous. As the students as well as the townsfolk went about armed, these battles frequently ended in bloodshed and death.

In spite of such incidents which were of course not of the usual, but of the unusual class, the mediæval student did a goodly amount of serious work, some naturally more and some less. The absence of healthy sports to relieve the daily routine was his most serious trouble.

The hold, which student customs have, brought many of them far down into modern times, not only in Europe but also in America. Curious survivals in the treatment of freshmen, fagging, the conflict between the freshmen and the sophomores, represented at Harvard until a short time ago by "Bloody Monday Night," and at other colleges by cane rushes, and the like, bear witness to this conservatism.

The popularizing of college education and the removal by university authorities of many of the restrictions on the natural impulses of youth for activity have led to the gradual disappearance of the many so-called mediæval customs. In their place has grown up a bewildering variety of activities for the student, which form a large part of his life. A perusal of the daily or weekly paper, or monthly, or annual periodicals published by the students in almost everyone of our institutions of collegiate rank, particularly in the United States, reveals not only the literary activity along such lines, but in the notices, which they publish, they bear witness to the existence of an extended variety of sports—baseball, football, rowing, tennis, lacrosse, basketball, hockey; numerous clubs and fraternities to which almost every student of any walk in life may belong; debating organizations, dramatic societies presenting operas and plays, musical clubs and orchestras, foreign language clubs and religious societies. Many of these intramural activities are represented also by intercollegiate contests in almost all of the sports, in debating, oratory and music.

On the social side dancing and singing, in large choruses, both during term time and at graduation exercises occupy a prominent place, especially at girls' colleges, which, after their establishment, in many ways followed in the footsteps of those for men. Luxurious living quarters have taken the place of the bare and comfortless rooms of less than half a century ago.

Though in America student life has gone

far beyond anything in the way of student life and customs, such as they exist in Germany, France and Italy, the English universities are a very close second. In the latter as well as in America there is that love of the "Alma Mater" which is not at all to be found on the continent of Europe. In the larger cities of America are to be found clubs of the graduates of the various institutions which hold them by close ties to the institutions from which they were graduated. There the student life and customs take a longer lease of life, especially at the time of the great intercollegiate athletic contests.

On the continent of Europe there is no such broad development of student life and customs as is found in Great Britain and America. The usual absence of dormitories or living halls in the great universities of Germany, France, Italy and Spain, the treatment of the universities as great day schools, the common practice of the students to take some semesters of academic work in one institution and some in another, the slight development of athletics, and other minor factors have caused the failure to develop that variety of student life and customs and that abiding affection for the "Alma Mater" found in English-speaking countries.

Student life and customs in schools of elementary and secondary grade were under the same repression as the colleges during the Middle Ages and came out from under it far less slowly than the latter. The tendency to imitate the higher institutions was very strong in all countries, and during the 19th century the secondary institutions reflected the student life and customs of the colleges and the elementary schools reflected those of the secondary. In large institutions of the latter grade, particularly in America, are to be found the same periodical publications, athletic sports and contests, literary clubs and fraternities, the same cohesive grouping of the student body, the same affection for "Alma Mater" as are found in the colleges. In a lesser degree and on a smaller scale the large elementary schools reproduce the same life.

The drunkenness and licentiousness which used to prevail in American colleges previous to the close of the 19th century had very largely disappeared in the earlier years of the 20th. College pranks resulting in the destruction of property had become fewer in number and "rough house" tactics in secondary school life had ceased to be so fashionable. In the matter of the elimination of drinking in the colleges, America had progressed far more rapidly than the countries of Europe. Duelling such as prevailed in German universities had never taken root in America.

The establishment of academies and, later, colleges for girls in America in the 19th century led to their own development of college life and customs. These very rapidly took on the color of almost exact imitations of those which had grown up in the institutions for men. The publications, literary clubs, sororities (instead of fraternities) and even athletic contests resembled those of the men. Though drinking never prevailed to any extent, cigarette smoking among the young women in American colleges is on the increase.

As the secondary and elementary schools for boys imitated in the life and customs of the students the doings of the colleges for men, so the elementary and secondary schools for girls tended to imitate the colleges for women.

In England such close imitation of the life and customs of men's institutions by the women is not found, and on the continent of Europe the life and customs in institutions for girls is very much more restricted. In fact there is about them the same atmosphere that prevailed about the institutions for boys in the earlier Middle Ages.

Bibliography.—No one book covers the subject in all ages, in all countries and in educational institutions of varying grades. Information must be sought in treatises on education covering various periods of history and separate countries, and even separate institutions. (For an extended list of books see the bibliographies referred to in the article: EDUCATION, HISTORY OF). Information of particular value will be found in the following: Alexander, 'The Prussian Elementary Schools'; Becker-Göll, 'Charicles' (II, p. 19); Brock, 'Eton'; Brown, 'The Making of Our Higher Schools'; Capes, 'University Life in Ancient Athens'; Converse, 'Wellesley'; Corbin, 'An American at Oxford'; Farrington, 'French Secondary Schools'; Findlay, 'Arnold of Rugby'; Fulton, 'College Life'; Göll on Becker's 'Gallus' (II, p. 61); Haskins, 'Life of the Mediæval Students as Revealed by their Letters'; Hill, 'Harvard by an Oxonian'; Hinchman, 'The American School'; Jones, 'Girton'; Keppel, 'Columbia'; Mahaffy, 'Old Greek Education'; Maspero, 'Life in Ancient Egypt and Assyria'; Paulsen, 'The German Universities'; Rait, 'Life in the Mediæval University'; Rashdall, 'Universities of Europe in the Middle Ages'; Risk, 'America At College'; Russell, 'German Higher Schools'; Sheldon, 'Student Life and Customs'; Taylor and Haight, 'Vassar'; Tennyson, 'Cambridge from Within'; Von Engeln, 'Concerning Cornell'; Walden, 'The Universities of Ancient Greece'; Wilkins, 'Roman Education.'

JAMES SULLIVAN,

Director of the Division of Archives and History of the University of the State of New York.

STUDENT OF SALAMANCA. The ('El-estudiante de Salamanca'), an admirable fantastic legend in verse by the brilliant, erratic Spanish genius, José de Espronceda (1810-42). It appeared in a collection of the author's poems published in 1840, and has since appeared in popular collections of the author's lyrical productions, such as the 'Biblioteca universal,' easily procurable. The hero of the poem, Don Félix de Montemar, is a new Don Juan, who has deceived his sweetheart, the beautiful, tender and loyal Doña Elvira, and killed her brother, Don Diego de Pastrana, who sought to avenge his sister. In the profligate Don Felix, a sublime and rebellious spirit, seeking pleasure and forgetfulness of his crime in the most violent emotions, the poet has drawn a picture of himself, yet painted blacker by far than reality reveals. For Espronceda seems to take pride in astonishing by his audacity and his moral cynicism and in giving a certain air of attractive grandeur to vices which he

affects but does not have. There is hardly anything in literature richer, more weird and fantastic than the description of the impious and unterrified Don Felix following the phantom who leads him along the shadowy way to the abodes of death where Don Pastraña, placing the phantom's hand in that of the satanic Montemar, tells him that at last the promise made to Elvira is fulfilled, and Don Felix, struggling in vain, expires amid countless shades of the nether world. In this exquisite poetic creation, made so largely by the many varieties of verse forms adapted to the particular situations, which render the production well nigh impossible of translation, may be divined something of the brief life of this romantic genius. The influence of Byron, Goethe and Leopardi is apparent. Capable of equaling each of these great geniuses, Espronceda in his brief career did not produce sufficient to make his poetic power so effective a reality. Consult for the poem, biography and commentary, the authoritative work by Don Patricio de la Escosura and Doña Blanca Espronceda de Escosura, '*Obras poeticas y escritos en prosa de José de Espronceda*' (Madrid 1884).

JAMES GEDDES, JR.

STUDENT SELF-GOVERNMENT.

Student self-government as an organized system is the product of modern times and of democratic ideas. In its ideal form it must not be confused with systems of government of one group of pupils by an older pupil set over them by an appointment from a teacher or the head of the school. Such systems of maintaining good order in the schoolroom and out of it existed in the Middle Ages and continued down into our own day under the names of prefectoral and monitorial systems. Though these involved the government and sometimes even the teaching of students by students, there was little about them to warrant their being called self-government systems.

Strictly defined self-government of students implies the existence of a system under which the students elect their own leaders or committees to see that school or college rules are obeyed and that violators are punished. Even though in the background the supreme authority of the school or college officials is always present, it is never so apparent as to disabuse the student body of the idea that it is to all intents and purposes governing itself.

The most advanced steps in student self-government under such a definition have been taken in America. The development of a great number of extramural activities on the part of college students led quite naturally to the organization of governing bodies for such purposes almost entirely free from control by college officials. In fact in some cases the abuses of self-government in such matters became so great that the college officials and the alumni had to interfere to set things right and to impose a supervision which had not previously existed. Nevertheless the influence of self-governing action in their own affairs made for the development of self-reliance and character and both college officials and students found it was but a short step to granting the participation of the students in matters heretofore deemed the business of the professional staff of the college.

One of the first of these steps was that of self-government in the examination room. This has commonly been defined as the "honor system." Before its institution one or several college officials were deputized to guard the examination room to prevent cheating. Under the new system these officials were withdrawn and the students put on their honor not to cheat and in some institutions to report those whom they saw cheating. In general the system has come into vogue far more widely in the colleges of the South and West than in those of the Northeast. Another development has been in taking resident officials out of the dormitories or living halls of the students and placing reliance on the honor of the latter to commit no infractions of the college rules and to report students guilty of such. Still another development in some colleges has been the election by the students of a committee which takes up the matter of disciplining students and acts in consultation with members of the faculty in important questions affecting the students.

In some colleges the attempt to put these measures of student self-government through have met with failure whereas in others they have been a success. In the latter case reports would indicate that although some weaknesses are discovered, the general conditions are no worse and are sometimes a good deal better than when all of the government was directly in the hands of college officials. The most serious difficulty encountered is in getting students to play the part of informer even though the information given is secret and inviolate.

The development of self-government in American public elementary and high schools grew from somewhat different motives. At first it came into vogue through the desire on the part of teachers to teach civics or civil government in a graphic manner. Inspired by such a motive they organized their classes into school cities and States, and sometimes the whole school was organized into a great governmental institution with legislative, executive and judicial departments and an array of government officials. This organization was in many cases used as a self-governing body, but, as was the case with the colleges, some were successful and some were not. It usually depended upon how much backing and time the school teachers and officials were willing to give to it, or how much they were able to simplify and modify the structure to meet the purposes of self-government. The enthusiasm of a teacher or a principal made up for much, and in almost all cases there is evidence of a certain artificiality and a feeling that the school official is constantly behind the scenes to make the wheels of self-government work smoothly. The value of the systems is not always so much in what the students accomplish as in the development of character which such systems may produce. Teachers in high schools have sometimes reported very adversely on students coming to them from self-governing elementary schools and sometimes very favorably.

The extramural athletic and social activities of the secondary and elementary schools were for a long time exclusively in the hands of the

students and thought to be no affair of the school authorities. With the great increase in their variety and importance, especially in interscholastic contests, the governing hand of the teacher or principal had to enter. A large measure of self-government, however, is left to the student body, the principal or teacher acting as an adviser and only exercising a power of veto in extreme cases. The amount of self-government in such matters is less for the secondary schools than for the colleges and is more than for the elementary school, a fact naturally due to the differences in the ages of the students.

Whether the large amount of self-government allowed to students in some of our colleges, secondary and elementary schools is going to be productive of the good results claimed for it only the future will tell. A survey of the field at present would seem to indicate that the American youth has not that law-abiding quality which is found in Old World communities where the hand of authority and the demand for obedience lies far more heavily. Opponents of the system maintain that lawlessness and failure to obey the command of governmental agencies have increased since the discipline and control of the school has been relaxed. Its supporters, however, say that such symptoms are due not to the self-government plan, but to the great preponderance of women teachers in the schools, to the heterogeneous character of our population and to the fact that in every new land where people foreign to each other in race, language and tradition lack for many years the proper ideals and common standards found in older and well-established nations.

Bibliography.—See general bibliographies under EDUCATION, HISTORY OF. Much material is to be found in the files of current educational publications (consult Poole's Index) and in the proceedings of professional organizations of teachers such as the National Education Association. Consult Birdseye, 'The Reorganization of Our Colleges' and 'Individual Training in Our Colleges'; Cranson, 'Pupil Self-Government'; Fulton, 'College Life'; George, 'The George Junior Republic'; Gill, 'School City'; Morehouse, 'The Discipline of the School'; Thwing, 'A History of Higher Education in America,' 'The American College,' and 'College Administration.'

JAMES SULLIVAN,
Director of the Division of Archives and History of the University of the State of New York.

STUDY CLUBS. See SUPPLEMENTAL EDUCATION.

STUFFING-BOX, in machinery, a contrivance for securing a steam, air or water tight joint when it is required to pass a movable rod out of a vessel or into it. It consists of a close box cast round the hole through which the rod passes, and in which is laid, around the rod and in contact with it, a quantity of hemp or other material called packing, this packing being lubricated with oily matter. The stuffing-box is used in steam-engines, pumps, on the shaft of a screw-steamer where it passes through the stern, etc. See PISTON.

STUHLWEISSENBURG, stool-vîs'sên-boorg, Hungary (Hungarian, SZÉKES FEJÉRVÁR, sâ'kesh-fé'hâr-vâr; Slavonic, BIELIGRAD), free

city, capital of a county of the same name, 30 miles southwest of Buda. It was built in the 11th century, and during five centuries was the place where the kings of Hungary were crowned. It has declined from its former importance, and has a poor appearance, though it contains some good buildings, among which are the splendid cathedral of the Virgin Mary, the church of Saint John and the bishop's palace. It has a theological seminary, a Catholic gymnasium, a military academy and various other educational establishments. The manufactures consist of cotton and woolen cloth, flannel, leather, knives, etc. In 1543-1601 and 1602-88 it was held by the Turks. Pop. 36,625.

STUMM-HALBERG, stûm-hâl-bêrk, Karl Ferdinand, German manufacturer and political leader: b. Saarbrücken, 30 March 1836; d. Schloss Halberg, 8 March 1901. He studied at the universities of Bonn and Berlin and, in 1858, took up a share in the management of his ancestral estate consisting of iron works on the Saar, Neunkirchen, Dillingen and Burbach. In 1875 he became a partner and carried the works on successfully under difficulties. He led a squadron of Uhlans in the war of 1870-71, after being three years a member of the Chamber of Deputies. He was member of the Reichstag till 1881 and again in 1889. In 1882 he became a member of the House of Lords and was created baron in 1888. As member of the Reichspartei he upheld the agrarian and Socialists' policy of Bismarck. He favored the protection tariff reform of 1879 as well as the protection of the laborer, on whose behalf he did much in the iron workshops yet fighting against Social Democracy at the same time. A monument was erected (1902) in his memory at Neunkirchen.

STUMP-TREE. See KENTUCKY COFFEE-TREE.

STUMPF, stûmpf, Carl, German psychologist and physician: b. 21 April 1848, at Wiesentheid, Bavaria. Studied at Bamberg Gymnasium and the universities of Würzburg and Göttingen. He taught in Göttingen from 1870, became professor of philosophy at Würzburg (1873), Prague (1884), Munich (1889), Berlin (1894). From 1907 to 1908 he was rector of the Berlin University. His works concerning the psychology of music are numerous, such as 'Musik-Psychologie in England' (in *Vierteljahrsschrift für Musikwissenschaft* 1885); 'Tonpsychologie' (1883-90); 'Beiträge zur Akustik und Musik Wissenschaft' (1898-1913). Other notable works are 'Tafeln zur Geschichte der Philosophie' (1900-03); and his 'Philosophischen Reden und Vorträge' (1910), etc.

STUNDISTS, stôn'dîsts, members of a political and social faction in Russia, known also as Russian Baptists. Originally the Stundist movement was religious and would have remained thus except for government interference. The orthodox priests, aided by the police and the courts, entered upon a vigorous campaign of persecution, with the result that the Stundist movement developed into political and social radicalism. From association with their foreign brethren, the Russian Baptists gained some knowledge of the political institutions of other countries where the state did not interfere with

the religious beliefs of its citizens. There were among them moderate liberals, with whom the paramount issue was the separation of the Church from the state and a constitutional government, as a guarantee of religious and civil liberty. The development of political aspirations among the Stundists brought into the ranks the most intelligent class of the Russian peasantry, whose influence spread in spite of persecution and undoubtedly was a serious factor in paving the way for the Revolution of 1917. The Stundists are strongest in Bessarabia and in Little Russia. Consult Dalton, H., 'Der Stundismus in Russland' (Gütersloh 1896) and Heard, A. F., 'The Russian Church and Russian Dissent' (London 1887). See also NIHILISM.

STUPART, Robert Frederic, Canadian meteorologist: b. near Toronto, Ontario, 1857. He studied at Upper Canada College, entered (1872) the service of the government meteorological department and served several years at the Toronto Magnetic Observatory. From 1884-85 he was meteorological observer in the Hudson Strait expedition, and became director of meteorological service and director of the Toronto Magnetic Observatory. He was elected president of the Royal Astronomical Society of Canada (1902-03), and president of the Canadian Institute (1906-07).

STURDEE, Sir Frederick Charles Dove-ton, English admiral: b. 1859. He entered the navy in 1871 and served in the Egyptian War of 1882; assistant to the director of Naval Ordnance, 1893-97; became captain in 1899 and commanded the British force in Samoa in that year; rear-admiral in 1908. From 1900 to 1902 he was assistant director of naval intelligence, became chief of staff in the Mediterranean fleet in 1905 and in the Channel fleet in 1907. He was made rear-admiral of the First battle squadron in 1910, and commander of the second cruiser squadron in 1912. At the outbreak of the European War Vice-Admiral Sturdee was chief of the war staff at the Admiralty. After the disastrous engagement off Coronel (q.v.), resulting in the loss of Admiral Cradock (q.v.) and three ships, Sturdee was dispatched with a squadron to deal with the German Admiral von Spee. The squadron arrived at Port Stanley in the Falkland Islands (q.v.) on 7 Dec. 1914, and early next morning, as if by arrangement, the five German battleships accompanied by two transports arrived off Port Stanley from the direction of Cape Horn. Von Spee expected to find only the remnants of Cradock's squadron, the *Canopus* and *Glasgow*, and also intended to seize the wireless station, at which a shell was fired at 9 A.M. Half an hour later, on coming abreast the harbor mouth, he saw the strength of the hidden British squadron. He hastily put to sea, and Sturdee's command steamed out in pursuit. The running fight lasted all day, and by nightfall Von Spee had gone down with four of his ships and the two transports, only one, the *Dresden*, making her escape. That vessel, however, was sunk on 14 March 1915. See WAR, EUROPEAN: NAVAL OPERATIONS.

STURE, stoo'rě, Sten, regent of Sweden: d. 1503. He was a nephew of Charles VIII and became regent upon the death of the latter in 1470. In spite of the opposition of the nobility

and the claims of Christian I of Denmark to the Swedish throne by the restoration of the Kalmar Union, he retained, with a short intermission, his position as the ruler of Sweden until his death. His reign was characterized by prosperity and intellectual progress among the people. He founded Upsala University, and introduced the art of printing into Sweden. The family of Sture became extinct in 1616.

STURGEON, William, English physicist: b. Whittington, Lancashire, 22 May 1783; d. 4 Dec. 1850. His education was begun in the army, where he received, through the aid of his officers, instruction in Latin, Greek and mathematics, which enabled him to read scientific books and to follow in particular his desire for a knowledge of electricity. His experiments begun during this period attracted attention on his settlement in Woolwich as a private citizen, and in 1823 he became widely known for his experiments with Ampère's rotary cylinders, and in the same year constructed the first soft iron electro-magnet. In 1832 he developed a machine which produced the greatest electric current then known, and during the remainder of his life was engaged in many valuable experiments. He founded the first electrical journal—the *Annals of Electricity*—in 1836. His chief writings are included in his 'Scientific Researches' (1850). He also wrote 'Experimental Researches in Electro-Magnetism, Galvanism, etc.' (1830); 'Lectures on Electricity' (1842); 'Twelve Lectures on Galvanism' (1843). Consult Smith, 'Centenary of Science in Manchester' (1850).

STURGEON, stér'jōn, a family (*Acipenseridae*) of fishes, now generally considered to constitute, with or without the paddle-fishes (*Polyodontidae*) the distinct order *Chondrostei*. Formerly the sturgeons were classified as cartilaginous ganoids, an arrangement which ichthyologists no longer find adequate. This group is considered to be one of the primary divisions of the *Teleostomi*, and the modern sturgeons to be the degenerate descendants of the more highly developed extinct forms. This degeneracy is expressed in the deficiency of the skeleton in numerous respects.

The sturgeons are bulky fishes of elongated form. The snout is conical and tapering. The mouth, which is small, toothless and protractile, is situated on the under surface of the muzzle, and is preceded by four tentacle-like filaments or barbules. The eyes and nostrils exist at the sides of the snout. The head is completely invested by ganoid plates, some of which are median, while on the body these plates are arranged in five longitudinal rows with smaller plates between. The tail is heterocercal, or unequally lobed, and is provided with bony spines along its upper margin. A single dorsal fin is present and placed far back, as are also the anal and ventral fins. Spiracles or apertures for the admission of water to the gills exist on the upper aspect of the head. The opercula or gill-covers are of large size, but imperfectly ossified and the branchiostegal rays are wanting. There are four pairs of gills and a pair of pseudobranchiæ on the opercula. The internal skeleton is chiefly cartilaginous, though the weak maxillary, premaxillary and dentary bones, serving as supports for the jaws, are ossified as are also the cerato-branchials. A persistent

notochord is surrounded by partly segmented cartilaginous vertebrae. A remarkable feature of the shoulder-girdle is the presence of an interclavicle. Among features of the soft anatomy are to be noted the presence of an elaborate spiral valve in the rectum, of pyloric caeca, of a large swim-bladder communicating with the oesophagus by a duct but without any highly vascular respiratory area, of several series of valves in the bulbus arteriosus, or base of the aorta, and of distinct funnel-shaped oviducts. All of these characters separate the sturgeons from the more highly specialized spiny-rayed fishes. Two to four genera and from 20 to 50 species have been recognized by different authors, the disparity arising from the great changes undergone by these fishes in the course of their growth. All are found in the northern hemisphere and most of the species are anadromous, living in the sea except at the time of reproduction, when they migrate up the rivers to fresh water for the purpose of spawning.

The latest authorities on the North American species give six as belonging to our fauna, five of the genus *Acipenser*, and one of *Scaphirhynchops*. All of them are of more or less importance as food fishes. The common sturgeon (*A. sturio*) is common to the Atlantic coasts of the United States and Europe. This and the related species are distinguished by minute characters in the shape, sculpturing, number, etc., of the large shields, the proportions of snout, fins and other similar characters for which the reader is referred to the literature cited. On our coasts the common sturgeon is found from New England to the Carolinas, entering rivers in the spring. In the Delaware River they appear in April and remain until September, the eggs being deposited during the early summer, being forced out by the female as she rubs her belly over rocks, stubs or other hard objects to which the eggs adhere after their immediate fertilization by the male. They are blackish in color, very glutinous, about a ninth of an inch in diameter and their number very great, not less than one to two and one-half millions being produced by each large female, and the ovaries at the time of maturity are so bulky that they constitute fully one-third of the fish's weight. Although so large the sturgeon feeds almost entirely on small mollusks, annelids, crustaceans and dead animal matter which it digs from the mud with its pointed snout, detects with its sensitive tentacles and sucks in with its small toothless mouth; to a great extent it is a scavenger. At times small fishes are also devoured in considerable quantities and that it may display considerable agility is attested by its occasional leaps from the water. The sturgeon reaches a length of from 5 to 10 feet, and a weight of 500 pounds, though examples of that size are now exceedingly rare. Formerly this fish was exceedingly abundant, a fact frequently mentioned by colonial and other early writers.

In the Delaware River, where the chief sturgeon fisheries exist, it was not valued previous to the last 60 years, but when captured was thrown away or an entire fish of several hundred pounds sold for 25 cents as hog food. The importance of the fisheries dates from about 1870, but they have been prosecuted so recklessly that they have been already nearly

depleted. Drift gill-nets are the chief means of capture. They are set on the flood tide and when the bobbing of the floats indicates the enmeshment of a fish, are drawn and the captive, which is singularly docile, removed. The flesh is sold fresh or smoked and is valued chiefly by the foreign population of the large cities. It brings a high average price in the market. The roes fetch a higher price and are immediately removed and worked through a wire sieve to separate the eggs, which are then placed in a brine of salt and boracic acid or similar preservative. After a sufficient treatment they are thoroughly drained and packed in oaken kegs or cans. This product is the celebrated caviar of the Russians. Vinegar seems to be no longer employed in the preparation of caviar in America. Besides using the flesh and roes for food the swim-bladders of the sturgeon are largely employed in Europe in the manufacture of isinglass. This substance is prepared by washing the sound in fresh water, and then carefully dried. The outer coat is then peeled off, the inner coat being cut into lengths or staples, which afford the isinglass. The sturgeon was celebrated among the ancient, for we find that in the palmy days of the Roman Empire sturgeons, profusely decorated with flowers, were borne in triumph to table. In the Volga, sturgeons are captured by driving piles at close distances so as to form a barrier across the river; by this barrier the fishes are forced into an enclosure, in which they are trapped and readily seized. Formerly any sturgeon captured in the Thames above London Bridge might be claimed by the lord-mayor, while one caught elsewhere might be claimed by the king as a "royal" fish. This custom doubtless arose from the high esteem in which the flesh was held by former sovereigns. Henry I is said, indeed, to have prohibited its use at any but his own table.

The white, Oregon or Sacramento sturgeon (*A. transmontanus*), is a still larger species, reaching a length of 13 feet and a weight of 1,000 pounds, found on the Pacific Coast. It is captured in considerable numbers in pound-nets and on set-lines in the Columbia and Sacramento rivers. It furnishes caviar, and smoked or frozen flesh, which is shipped East. This species is said to feed chiefly on minnows. The lake sturgeon (*A. rubicundus*) lives in the upper Mississippi Valley, in the Great Lakes and other smaller lakes of the central United States and Canada. It seldom exceeds 50 pounds in weight, but is the object of important fisheries in Lakes Erie, Ontario and Lake of the Woods. It feeds on snails, crayfish and insects. The green sturgeon (*A. medirostris*) of the Pacific is of little value as food, though not poisonous as often stated, while the Atlantic short-nosed sturgeon (*A. brevirostrum*) is disregarded on account of its small size. *Scaphirhynchops* has a broad flat snout, no spiracles, and a complete covering of bony plates on the base of the tail. Besides several Asiatic species, the white or shovel-nosed sturgeon (*S. platyrhynchus*) is common throughout the Mississippi Valley and beyond, and although seldom exceeding two feet in length is much valued for food.

The family *Polyodontidae* or paddle-fishes are sturgeon-like fishes sometimes placed in a separate order and distinguished from the true

sturgeons especially by their remarkably prolonged spatulate snouts, the absence of maxillary bones and the smooth unarmored skins. *Psephurus gladius* is found in the rivers of China, *Polyodon spathula* in the rivers of the Mississippi Valley. This remarkable fish stirs up the mud of the bottom with its long paddle and strains out the small organisms so exposed by means of its filter-like gill-rakers, and swallows them. It breeds in the ponds and bayous connected with the upper parts of the rivers or in the shallows of lakes. It is captured in seines and on set-lines and the product of the fisheries is utilized in the same manner as other sturgeons. The important centres of this fishery are along the lower Mississippi and in Lake Pepin, Minn.

The sturgeon fisheries of all parts of the country are in serious danger of being destroyed, but the above data indicate that the evils of overfishing, etc., have been most harmful in the Delaware River. Several attempts to propagate the sturgeon artificially have been made by the Fish Commission, but the peculiar difficulties resulting from the methods of the fisheries and the mode of reproduction of this fish have up to the present proved insurmountable.

STURGEON BAY, Wis., city, county-seat of Door County, on Sturgeon Bay and on the canal which connects Green Bay with Lake Michigan by a short route and on the Ahnapee and Western Railroad. It is about 40 miles northeast of the city of Green Bay. The bay is a good harbor about eight miles long and from one to three miles wide. The city is in an agricultural region, formerly an extensive lumbering region. Sturgeon Bay exports large quantities of grain and lumber. Its industrial establishments include box factories, flour mills, foundries, machine shops, shipyards, canneries, stone quarries, etc. There is a State fish hatchery here. The city has also a public library, government lighthouses, Indian burial-ground and Peninsula State Park. Pop. 4,262.

STURGEON FALLS, Canada, town and outport of Nipissing District, Ontario, on Lake Nipissing and on the Canadian Pacific Railroad. It is 385 miles west of Montreal, and has paper and other mills. Pop. 2,199.

STURGIS, Richard Clipston, American architect: b. Boston, 24 Dec. 1860. He was graduated at Harvard in 1881, studied architecture in London, England and began practice in Boston in 1887. He was a member (1904-

09) of Sturgis and Barton Company, but has since been alone. He was architect of Franklin Union, Boston, Brookline Public Library building, First National Bank building, Boston and the Cathedral, Manila, etc.

STURGIS, Russell, American architect and author: b. Baltimore, Md., 16 Oct. 1836; d. New York, 11 Feb. 1909. He was graduated at the College of the City of New York in 1856; studied architecture in Europe and practised his profession, 1865-78, retiring because of failing health. He devoted his attention to the artist societies of New York City and to writing and lecturing on art subjects. He edited the art sections of the Century and Webster's 'International' dictionaries and of Johnson's (later Appleton's) 'Universal Cyclopaedia'; contributed largely also to the 'New International Encyclopædia' and the 'Encyclopedia Americana.' He was editor and chief author of the 'Dictionary of Architecture and Building' (1901-02), and edited the department 'The Field of Art' in *Scribner's Magazine* after January 1898; also issued a revised edition of Lübke's 'Outlines of the History of Arts,' completely revised and brought down to date (1904). He was the author of the 'Manual of the Jarves Collection of Early Italian Pictures,' published by Yale College (1868); 'European Architecture, a Historical Study' (1896); 'Annotated Bibliography of Fine Art' (1897); 'How to Judge Architecture' (1903); 'The Appreciation of Sculpture' (1904); 'The Interdependence of the Arts of Design'—the Scammon Lectures for 1904 (1905); numerous critical monographs in different periodicals.

STURGIS, Mich., city in Saint Joseph County, on the Grand Rapids and Indiana and the Lake Shore and Michigan Southern railroads. It is 36 miles southeast of Kalamazoo and has manufactures of furniture, plumbers' woodwork, shears, a foundry, etc. Pop. 3,000.

STURLUSON, stoor'lā-sōn, Snorri, Icelandic author and politician: b. 1178; d. Reyk-holt, 22 Sept. 1241. He was well educated in Scandinavian history, mythology and poetry. He soon rendered himself popular by his bravery on the field and eloquence in the assemblies of the people and was elected by the unanimous voice of the people supreme judge of the island. In 1213 he composed his first poem which became widely known, a panegyric of Hako IV, king of Norway. In 1218 he paid a visit to Norway, where he was well received by Jarl Skule, who loaded him with rich presents and high dignities on the eve of his return to Iceland in 1220. In 1237, being forced by feuds to leave Iceland, he made a second voyage to Norway, where he was once more warmly welcomed by Skule, now become duke. Snorri composed some poetical pieces warmly laudatory of his patron, and promising him success in the struggle going on between him and Hako V. That prince forbade Snorri to return to his native land, but the order was unheeded, and Sturluson, being informed of the decline of the power of his enemies, returned to Iceland in 1239, and was there murdered. His principal work, which he completed about 1230, is the 'Heimskringla' (Circle of the World), in which he records the lives of the legendary and historical kings of

Norway down to the death of Magnus Erlings-son in 1177. It was translated into Danish by Peder Clausson, and published in Copenhagen by Olaf Worm in 1633. A recent edition is that by Jónson (1893 onward). The work has also been translated into German, Norwegian, Swedish, Latin and English (by S. Laing, 1844; new ed. by R. B. Anderson, 1889; by W. Morris and E. Magnússon, 1893-94). He composed numerous eulogistic poems on the princes and jarls whose courts he had visited; and wrote, it is believed, the first part ('Gylfa-Ginning') of the 'Snorra-Edda,' or 'Younger Edda.' See EDDAS, THE.

STURM, stoorm, Jacques-Charles-Francois, French mathematician: b. Geneva, 29 Sept. 1803; d. Paris, 18 Dec. 1855. He studied at the Geneva College, passing the course before his 14th year, to enter the Academy course. He became teacher to the son of Madame de Staël. In 1827 he was awarded the grand prize in mathematics and by 1829 he had propounded his great theorem "the solution of numerical equations," which has done so much to assist in the advance of scientific research. He was successively appointed professor of special mathematics at the Rollin College (1830); was made member of the Académie des Sciences (1836), succeeding Ampère, and in 1840 he was made professor of analysis in the École Polytechnique and professor of mechanics to the faculty of sciences. Consult Liouville, 'Discourse prononcé sur la tombe de Sturm,' in *Siècle* (1855); Prouhet's 'Notice' in *Nouvelles Annales Mathématiques* (1856).

STURM, or **STURMIUS**, Johannes, German educator: b. near Cologne, 1 Oct. 1507; d. 3 March 1589. In 1537 he founded the gymnasium in Strassburg which attained world-wide celebrity. He was generally regarded as the greatest educator connected with the Reformed Church. Sturm's ideal in education was "to direct the aspiration of the scholars toward God, to develop their intelligence, and to render them useful citizens by teaching them the skill to communicate their thoughts and sentiments with persuasive effect." In carrying out this ideal Sturm showed his superiority by his judicious gradation of the course of study, and by his novel and attractive methods of instruction. His influence has been potent in the German system of secondary education down to our own day.

STURM, Julius, German lyric poet: b. Köstritz in Reuss, 21 July 1816; d. Leipzig, 2 May 1896. He studied theology at Jena and was pastor at Göschitz, 1851-57 and at Köstritz, 1857-85. His poems have a decidedly religious or nationalistic trend. Among his published volumes are 'Two Roses; or, the Canticle of Love' (1854); 'Devout Songs and Poems' (1858); 'Israelite Songs' (3d ed., 1881); 'Poems of Battle and Victory' (1870); 'Mirror of the Time in Fables' (1872); 'To the Lord my Song' (1884); 'Palm and Crown' (1887); 'In Joy and in Sorrow' (1896); 'Für das Haus'; 'Lieder und Bilder'; 'Kampf und Liebesgedichte'; 'Spiegel der Zeit in Fabeln'; 'Kinderleben'; 'Immergrün'; 'Natur, Liebe, Vaterland.' Consult the biographies by Hepding (Giessen 1896) and Hoffman (Hamburg 1898).

STURT, stért, Sir Charles, English explorer: b. Bengal, India, 1795; d. Cheltenham, England, 16 June 1869. He entered the army and in 1825 went with the rank of captain to New South Wales, where in 1827 he headed an expedition into the interior of Australia, in the course of which he discovered the Macquarie, Castlereagh and Darling rivers, and in June 1830, while on a later expedition, discovered the important Murray River, which he descended to its mouth. In 1844 he discovered the stony desert in the centre of the Australian continent. He was made registrar-general and colonial secretary of South Australia, but his exposure during his expeditions soon rendered him totally blind and he returned to England, where he was knighted just prior to his death. He published 'Two Explorations into the Interior of Southern Australia in 1828-31' (2 vols., 1834); 'Narrative of an Expedition into Central Australia in 1844-46' (2 vols., 1849). Consult Sturt, N. G., 'Life of Charles Sturt' (London 1899).

STUTTERING, faulty articulation which results in defective speech. See STAMMERING.

STUTTGART, Ark., city of Arkansas County, 50 miles southeast of Little Rock, on the Chicago, Rock Island and Pacific and the Saint Louis Southwestern railroads. It has rice mills, pump and screen factories, iron and brass foundries, a saw mill and a handle factory. There is a large trade in agricultural produce. Pop. 2,740.

STUTTGART, stoot'gärt, Germany, capital of Württemberg, in the basin of a broad valley, enclosed by vine-clad or wooded hills, near the Neckar, 40 miles southeast of Karlsruhe. Many of the important buildings are grouped near the central Palace square; chief of these are the old and new Schlösser or Palaces, of the 16th and 17th-18th centuries, respectively, with extensive and beautiful grounds, embellished by statuary and fountains. Other interesting features are the numerous princely palaces; the Königsbau, with colonnades; Akademie; the Gothic churches of Saint Leonard's, Saint John and the Hospital Church; the Queen Olga buildings, on the north side of Castle square, the National Industrial Museum, with lofty cupolas; the Liederhalle, containing an enormous hall; the new town-hall, Peace Church, Saint Nicholas, etc. Other interesting features are the numerous collections of antiquities, art, numismatics, archives, conservatory of music, chemical laboratory, schools of art, science and commerce; and the magnificent royal library, which contains about 500,000 volumes and the largest collection of Bibles in the world (7,300). Stuttgart is one of the most important publishing centres in the world and has a constantly increasing trade. The manufactures include textiles, chemicals, furniture, carriages, paper, jewelry, bells, cigars, chocolate, pianos, pigments, leather, etc. There is a large trade in hops, cloth and horses. Near the Neckar, at Berg, there are mineral springs, and Carnstatt is a watering-place near the town, connected with it by tramway. Many monuments of German heroes and celebrities stand in the various squares of the city and in the parks. The town is on the line of several railways. It stands on the site of an

Engraved by G. Kneller. From an original by T. Kneller.

J. Dujin Janiff

ancient monastery. In the 15th century it became the residence of German princes and was greatly improved, being designated the official capital in 1482. Art and science were introduced in the 19th century. Stuttgart was the home of the philosopher Hegel and Hauff, the art critic. The city is governed by an overburgomaster, assisted by two advisers and a council. Pop. 286,218. Consult Klaiber, 'Stuttgart (in 'Europäische Wanderbilder' (Zürich 1892) and Widmann, 'Wandering durch Stuttgart und Umgebung' (Stuttgart 1896).

STUYVESANT, sti'vĕ-sănt, *Petrus*, Dutch director-general of New Netherland: b. Holland 1592; d. New York, August 1672. He served in the war in the West Indies, became director of the colony of Curaçao, and, having lost a leg in an unsuccessful attack on the Portuguese island of Saint Martin, returned to Holland in 1644. In 1645 he was appointed by the Dutch West India Company director-general of New Netherland, succeeding William Kieft, who had involved the settlers in a war with the Indians, and created general disorder. He did not arrive until 11 May 1647, when he commenced a vigorous and often arbitrary administration, conciliating the savages and thoroughly restoring order. In 1650 he arranged at Hartford with the New England commissioners a boundary between the Dutch and English territories, previously undefined and a cause of frequent disputes. He was also involved in trouble with the Swedes on the south. In 1651 the Dutch built Fort Casimir on the Delaware, but the post was captured by Rising, governor of New Sweden, in 1654. To revenge this, Stuyvesant in 1655, with seven vessels and about 700 men, sailed into the Delaware, and made a conquest of the whole settlement of New Sweden, calling it New Amstel. Ten years of peace followed, disturbed only by the growing jealousy of the English, and by the civil discontents which the haughty character of Stuyvesant's administration provoked. In 1653 a convention of the people, consisting of two deputies from each village in New Netherland, met and formulated demands that "no new law shall be enacted but with the consent of the people; that none shall be appointed to office but with the approbation of the people; that obscure and obsolete laws shall never be revived." This assembly was dissolved by Stuyvesant, who commanded the members to disperse, saying: "We derive our authority from God and the company, not from a few ignorant subjects." The encroachments of the New England colonies at last induced Stuyvesant himself to lay his remonstrances before the convention of the united colonies at Boston, but he met with little favor. A second embassy to Hartford had no better success. The Connecticut agents made exorbitant claims to territory by virtue of the royal patent. In 1664 Charles II granted to his brother, the Duke of York, the territory from the Connecticut to the shores of the Delaware, and in August an English fleet under Capt. Richard Nicolls appeared in the bay and demanded the surrender of the city. The municipality insisted on yielding. After holding out for a short time, the governor at last consented, and the

city was surrendered 3 Sept. 1664. After the capture Stuyvesant in 1665 left to report to his superiors in Holland, but afterward returned, spending the remainder of his life on his farm or *bouwerij* (whence the name of the street called Bowery). He lies buried in the vaults of Saint Mark's Church. The semi-burlesque account of him by Irving in the 'Knickerbocker's History' is well known. Consult Abbott, J. S. C., 'Peter Stuyvesant' (New York 1898); Tuckerman, Bayard, 'Peter Stuyvesant' (ib. 1893); Van Rensselaer, Mrs. S., 'History of the City of New York in the Seventeenth Century' (2 vols., ib. 1909); O'Callaghan, E. B., 'The History of New Netherland' (ib. 1848).

STY, or **STYE**, an inflammatory swelling about the follicle of an eyelash, known in surgery as *hordeolum*. It resembles a grain of barley, and is strictly only a little boil which projects from the edge of the eyelid, mostly near the great angle of the eye. It is of a dark red color, much inflamed, and much more painful than might be expected, considering its small size, partly owing to the vehemence of the inflammation, and partly to the exquisite sensibility and tension of the skin which covers the edge of the eyelid. On this account a sty often excites fever and restlessness in delicate, irritable constitutions; it suppurates slowly and imperfectly; and when suppurated has no tendency to burst. It generally bursts in a few days, however, though it is generally better to puncture it. Warm-water dressings with lint and oiled silk should be applied.

STYLE, (1) in *chronology*, see **CALENDAR**; (2) in *art*, see **PAINTING**; (3) in *architecture*, see **ARCHITECTURE**.

STYLITES, sti-lî'tĕz. See **PILLAR SAINTS**.

STYLOBATE, in *architecture*, the substructure of a Greek temple below the columns, sometimes formed of three steps which were continued round the peristyle, and sometimes of walls raised to a considerable height, in which case it was approached by a flight of steps at one end.

STYLUS. See **PEN**.

STYPTIC, an application for checking the flow of blood or closing the aperture of a wounded vessel. Oak-bark decoction, gall-nuts in powder or infusion, matico and turpentine are styptics derived from the vegetable kingdom; and from the mineral are derived salts of iron, the sulphates of copper and zinc, the acetate of lead and the nitrate of silver.

STYRAX, the typical genus of the family *Styracaea*, graceful, spreading shrubs or trees, with entire or serrate leaves, and bearing white five-parted flowers in drooping racemes, often very showy and fragrant. *Styrax benzoin* of the East Indies and adjacent Asiatic coasts yields, when the bark is wounded, a yellowish-brown resin, which, when heated or rubbed, gives out a balsamic vanilla-like odor. It is a favorite ingredient of incense, perfumes and cosmetics; also a stimulating and healing drug and one of the principal constituents of court-plaster. *Styrax officinalis*, found in Asia Minor and Syria, has a resinous bark and flowers of orange-blossom-like sweetness. This species formerly yielded the fragrant solid resin, vanilla-scented, and like benzoin, known as

storax, once much used in incense, but which has now disappeared from commerce, its place being taken by the "liquid" storax, furnished by *Liquidambar*, which also was anciently known. *Styrax americana* is a small shrub, of the southern United States, which has slender branches, and, in spring, drooping solitary or racemed, bell-shaped flowers, having a faint fragrance, and nearly hidden by the small, oval leaves which are nearly smooth. *S. grandifolia* is more pubescent, has larger leaves and more fragrant flowers. Certain Japanese species are in cultivation, and are hardy as far north as Massachusetts, such as *S. japonica* and *S. obassia*.

STYRIA, stîr'î-ä, Austria, a province, formerly duchy; area, 8,662 square miles. It is traversed by three Alpine ranges, whose highest points reach in the Grimming at the northwest, and the Eisenhut at the southwest, an elevation of 7,400 and 7,646 feet respectively. The ranges are penetrated by many valleys of different extent; the only level land is at the southeast. Styria belongs wholly to the basin of the Danube, and is drained by the Enns, Mur, Drave and Save. The mountain lakes lie amid beautiful scenery. There is much barren land, and about 20 per cent of the total area is arable; vineyards flourish in certain districts. Fruits abound, and hemp, flax and the poppy are grown extensively. The forests and mines are the staples of wealth, and their products constitute the chief exports. The minerals comprise gold, silver, copper, lead, zinc and the finest quality of iron — besides sulphur, salt and alum. The iron manufactures are the most important, including scythes, swords, rails, sheet-iron, wire, hardware, etc. Other manufactures are glass, tobacco, liquors, beer and paper. Pop. about 1,450,000. The population is about 98 per cent Roman Catholic. Graz, the capital, has a population of 151,181. Other large cities are Marburg, Eggenberg and Leoben.

In Roman days Styria was divided between Pannonia and Horicum and was inhabited by the Taurisci, a Celtic people. In the various migrations that swept over Europe Styria was crossed by Visigoths, Huns, Ostrogoths, Lombardi, Franks, Arars, Slavs, etc. The Slavs predominated after the 6th century A.D. It was included in the great duchy of Carinthia but was recognized as a separate mark in 1056. It became a duchy about 1192, when it passed to the house of Austria. In 1282 it passed to the Hapsburgs. Consult 'Die Oesterreichisch-ungarische Monarchie in Wort und Bild' (Vol. VII, Vienna 1890); Gsell-Fels, Thomas, 'Die Steiermark' (Munich 1898); Imendörfer, Benno, 'Landeskunde von Steiermark' (Vienna 1903); von Machar, Albert, 'Geschichte der Herzogtums Steiermark' (9 vols., Graz 1844-74); Rosegger, P. K., 'Das Volksleben in Steiermark' (Leipzig 1895); Mayer, F. M., 'Geschichte der Steiermark' (Graz 1898).

STYX, stîks, the name of a river of the infernal regions, in the mythology of the Greeks and Romans. The real Styx was a stream in Arcadia, which is now called the Mauraneria, or Black Waters, and also the Drako-neria, or Terrible Waters, and which was and is considered injurious to men and beasts. Souls going to the infernal regions were, according to

the ancient myth, ferried across the Styx by Charon.

SU-CHAU, soo'chow', China, the capital of the province of Kiang-su, situated on the Grand Canal east of Lake Tai-hu, and 50 miles west of Shanghai. The city is surrounded by walls 30 feet high, and the inner portion is intersected by numerous natural and artificial waterways which communicate with the larger channels connecting the city with the Yang-tse-kiang, Lake Tai-hu, Shanghai and Hang-chau. Su-chau is the seat of the provincial college, and contains several interesting pagodas. In the vicinity stands the ancient temple of Hu-kiu-shan. The inhabitants manufacture silks and other cloths, and fine carved and lacquered articles. The city was made a treaty port in 1896 by the Treaty of Shimonoseki. Pop. estimated at 500,000.

SUAKIN, swä'kîn, or **SUAKIM**, Nubia, a seaport on the coast of the Red Sea, consisting of two parts joined by a causeway, one part occupying the shore of the mainland, the other the rocky island in the bay. It is the principal town of the district of the same name, in the Sudan. The natives live at El-Keff, the section on the mainland, and here stands the bazaar — a scene of bustling activity, also the barracks occupied by Anglo-Egyptian troops; beyond are the fountains surrounded by date-groves and orchards. The natives live in tents. The principal manufactures are silver ornaments, knives, spear-heads and leather-work. Trade is considerable, and the chief exports include the above-mentioned articles, besides ivory, gums, millet, cattle, hides and gold. The imports: durra, cottons, flour, sugar, rice, ghi, dates and coal. This is a starting-point for African pilgrimages to Mecca. The vicinity was the battlefield of the allied British and Egyptian forces against the Mahdi and his Dervish followers. It was for many years a slave port. Pop. about 10,500.

SUAREZ, swä'rêth, Francisco, Spanish theologian: b. Granada, 1548; d. Lisbon, 1617. He was one of the most eminent scholastic and polemical writers of the Roman Catholic Church. He entered the Society of Jesuits in 1564, and soon became professor in succession at Valladolid, Rome, Alcalá and Salamanca. In 1597 Philip II appointed him principal professor of divinity at the University of Coimbra, a position he held until his death. The most recent edition of his works was completed in Paris in 1860.

SUAREZ MUJICA, Eduardo, Chilean diplomat: b. Santiago, 1850. He was educated at the Santiago University and became (1882-1888) Acting Secretary of Foreign Affairs, governor of Atacama (1901-03), member of Congress (1903-09) and Minister of Justice and Public Instruction (1908). In 1909 he was made Minister to Mexico and Cuba, then (1911) Minister and (1914) Ambassador to the United States. He was a member (1915) of the Niagara Falls Pan-American Conference to discuss and settle the imbroglio with Mexico.

SUB-DEACON, the lowest step in major orders in the Roman Catholic Church and the highest of the minor orders among the Greeks. In the Roman Catholic Church sub-deacons prepare the sacred vessels and the bread and wine

for Mass, pour the water into the chalice at the Offertory and sing the Epistle; in the Greek Church they prepare the sacred vessels, and guard the gates of the sanctuary. There are no sub-deacons in the Protestant Episcopal Church.

SUBCONSCIOUSNESS, a state of the mind or a process of cerebration similar to those mental states and processes of which we have consciousness, though of this state or process we are unconscious. See **CONSCIOUSNESS**.

SUBLIMATION, a chemical process by which volatile solids which do not melt are vaporized by heat, and again condensed in a solid form, without passing through an intermediate liquid phase. The operation is commonly conducted either for the purpose of purifying certain substances and disengaging them from extraneous matters, or of reducing them into vapor and combining them while in that form. As all fluids may be volatilized by a sufficient degree of heat, and consequently may be separated, in most cases, from fixed matters, so various solid bodies are subjected to a similar treatment. The substance formed by the process of sublimation is called a sublimate. The principal subjects of this operation are volatile alkaline salts, neutral salts, composed of volatile alkali and acids, as sal-ammoniac, arsenious acid, benzoic acid, mercurous chloride, indium trichloride, anthracene, iodine, camphor and sulphur. In some cases, by applying the heat under pressure a substance which usually sublimates before melting may be first melted and then distilled as in the case of liquids. For instance camphor sublimates at any temperature below 350° F. If confined under pressure it will melt and boil at 400°. However if the vapor from the boiling liquid is passed into a vessel of lower temperature it does not deposit as a liquid but as a solid. Sulphur melts to a liquid in the process of sublimation but does not pass through a liquid state in condensing. See **DISTILLATION**; **EVAPORATION**.

SUBLIME, *The*, that which, in the works of nature or of art, is grand and awe-inspiring. Longinus, the eminent philosophical critic (3d century), in his work 'Peri Hypsūs,' 'Of Sublimity,' characterizes the sublime in literary composition as that which "fills the reader with a glorying, and sense of inward greatness"; but he does not inquire into the nature of the sublime in general. Burke finds the essence of the sublime to consist in terror, acting whether openly or latently. Blair sees the cause of the feeling of pleasurable elation excited by the sublime, a mighty power or force; Kames in height or elevation; according to Sir William Hamilton the emotion produced by the sublime is a mingled feeling of pleasure and pain—pleasure in the consciousness of strong energy, and pain in the consciousness that this energy is vain. He distinguishes three phases of the sublime, the sublime of extension or space, of intension or power, and of protension or power, and cites the following passages from Kant as admirably illustrating the sublime in each of these three forms:

"Two things there are, which, the oftener and the more steadily we consider them, fill the mind with an ever new, an ever rising admiration and reverence—the Starry Heavens above, the Moral Law within. Of neither am I compelled to seek out the reality, as veiled in darkness, or only to conjecture the possibility, as beyond the hemisphere of my

knowledge. Both, I contemplate, lying clear before me, and connect both immediately with my consciousness of existence. The one departs from the place I occupy in the outer world of sense; expands beyond the bounds of imagination this connection of my body with worlds lying beyond worlds, and systems blending into systems; and protends it into the illimitable times of their periodical movements—to its commencement and continuance. The other departs from my invisible self from my personality, and represents me in a world, truly infinite indeed, but whose infinity can be tracked out only by the intellect, with which also my connection, unlike the fortuitous relation I stand in to all worlds of sense I am compelled to recognize as universal and necessary. In the former, the view of a countless multitude of worlds annihilates, as it were, my importance as an animal product, which, after a brief and that incomprehensible endowment with the power of life, is compelled to refund its constituent matter to the planet—itsself an atom in the universe—on which it grew. The aspect of the other, on the contrary, elevates my worth as an intelligence even without limit; and this through my personality, in which the moral law reveals a faculty of life independent of my animal nature, nay, of the whole material world; at least, if it be permitted to infer as much from the regulation of my being, which a conformity with that law exacts; proposing as it does, my moral worth for the absolute end of my activity, conceding no compromise of its imperative to a necessitation of nature, and spurning in its infinity the conditions and boundaries of my present transitory life." See **ÆSTHETICS**.

SUBLIME PORTE, *pört*, or **OTTOMAN PORTE**, the common term for the Turkish government. The chief office of the Ottoman Empire is styled Babi Ali, meaning the High Gate, from the gate (bab) of the palace at which justice was administered; and the French translation of this term being Sublime Porte, hence the use of this word. See **TURKEY**.

SUBMARINE CABLES. See **CABLE**, **SUBMARINE**.

SUBMARINE FORESTS are remains of forests found submerged beneath the present sea-level, and either not at all exposed or exposed only at low tide. They occur on all coasts, and indicate either a subsidence and submergence of the land after the trees had grown to their present size, or an encroachment of the sea and removal of a barrier which separated a low-lying forested area from the sea, which then submerged this area. Submerged trees are known on the Maine, Massachusetts and New Jersey coasts, as well as elsewhere in this and other countries.

SUBMARINE MINES. The Russo-Japanese and the European wars demonstrated that the most deadly weapons of seacoast and naval warfare are the submarine mine and torpedo. A single submarine mine exploded at the proper time will disable or sink the largest battleship. The Turkish Coast artillery in closing and keeping closed the Dardanelles was pitted against the persistent and combined attack of the Allied fleets of Great Britain, France and Russia. Submarine mines are principally used in defensive operations within harbors, whereas torpedoes are primarily an element of offensive warfare by warships. Mines are generally classed as fixed and floating. The fixed or stationary submarine mine is fired by contact, electricity, timing device or fuse. Such mines, which are extensively used by all navies, are rugged in design and may contain large charges of explosives. They are placed in position by submarines and other especially equipped mine-laying vessels. Such mines are provided with anchoring devices and are deposited, if possible, in harbors and channels of the enemy or in the paths of ocean travel. Floating mines differ from fixed mines

in that they are unanchored, and unless guard boats are at hand to warn friendly vessels of their proximity, may be as dangerous to friend as to foe. Such mines must be, according to the laws of war, designed to become inoperative within a few hours after being set adrift. The German floating mines were often cast adrift in pairs, connected by a line about 100 feet long. If a ship runs between the two mines they are drawn alongside the ship and exploded. Contact depth mines, which rise to the surface if failing to contact, are sometimes used with telling effect. The essence of the depth charge is that it explodes in the vicinity of the submarine or other craft, in case it fails to strike the boat itself. The use of the contact depth mine presupposes the necessary accuracy to strike the target. The high-explosive mines used by the Germans and other belligerent powers, known as submerged contact mines, when first put in place were so anchored that they were held at a certain distance below the surface of the water. It was intended that they should remain invisible and be exploded when struck by any vessel that might come in contact with them. Such mines may be removed by various methods of dragging or sweeping, such as by sinking a long cable, each end of which is attached to a tug, and thus dragging a suspected location.

Submarine mines, fixed and floating, are of three different kinds: (1) *Observation mines*, fired from shore, when a ship is judged to be within effective range of the explosion; (2) *Automatic mines*, which are self-firing when struck by a ship; (3) *Electrical contact mines*, which, on being struck by a ship, give notice to an operator on shore, who, by the throw of a switch, fires the mines. As a rule the submarine mine consists of a metal case, filled with high explosives and fitted with a fuse that may be fired automatically, or at will by an operator located at some distant point. In shallow water the mine is laid on the bottom and is known as a ground mine. When the depth is so great as to interfere with the destructive force of the explosion, the explosive is carried in a buoyant cylinder or sphere, which is anchored to the bottom by a length of cable which causes it to float at the proper depth to be struck by a passing ship. The mines (the type in general use being the electro-contact mine) are usually planted in rows across the channel to be defended, the mines in successive rows being "staggered," so that if a vessel should pass through the first row it must inevitably strike one or more in the later rows. They are planted in what is known as "grand groups," which consist of 21 mines in groups of three. Some distance in the rear of the line of mines there lies on the bottom of the channel a grand junction box, from which seven cables spread, each leading to a triple junction box, which in turn controls its small group of three mines. From the grand junction box, also, the multiple cable winds its way to the switchboard connection in the operating-room on shore. The grand junction box is placed at the centre of the line of mines and about 100 feet to the rear. The triple junction boxes are laid in a straight line at intervals of 300 feet; from each of these boxes separate cables lead to each of three mines, the

mines, 21 in all, being spaced 100 feet apart, in a line which extends for 2,000 feet across the channel. Each mine is anchored by a cable to an anchor, the length of the cables being such that each mine will float at a depth of 10 or 12 feet below the surface of the water. By an ingenious arrangement, one, three or the whole grand group of mines can be fired, either from the operating-room ashore, or by contact with a ship, all at the will of the operator. No mine field is complete, or can ever be thoroughly effective, unless it is protected by rapid-fire guns. It is possible for small boats, launches, etc., to be sent forward ahead of the ships, and set off the mines by exploding large charges of dynamite in the mine field. If the mines are within the "sympathetic radius" of the explosions, they will be exploded by the shock. The most effective protection against such countermining, as it is called, is by flanking the field with batteries of rapid-fire guns.

In the European War, the outstanding anti-submarine offensive project was the closing of the North Sea by a mine barrage extending from the Orkney Islands to the territorial waters of Norway, together with a barrage across the Straits of Dover. The plan to close the North Sea, and thereby deny enemy submarines free access to the Atlantic from German bases, had its inception in the United States Bureau of Ordnance in April 1917, immediately following the entrance of the United States into the war. At this time there had not been developed anywhere a type of mine suitable for the Scotland-Norway line, whereon the depths of water are as great as 900 feet and where a prohibitive number of mines of the then existing type would have been required to mine this line from the surface to a depth of 250 to 300 feet. A special mine-loading plant, with a capacity of more than 1,000 mines a day, was established near Yorktown, Va., by the Navy Department, in accordance with Congressional authorization, about 11,000 acres of land having been secured for the purpose. An immense number of mines were stowed at this depot, and it included a mine-loading plant, a mine-assembling plant and storage for a large amount of high explosives. More than a score of cargo vessels were placed in service as mine carriers to transport mines to Europe. Many mine layers and auxiliary vessels were fitted out and assigned to the execution of the project. The manufacture of the large number of mines required was a work of unprecedented magnitude and necessitated unusual methods. It was clearly impossible, in the time available, to manufacture the mine as a whole in any plant; therefore, the mine was divided into its many component parts and the parts were separately produced in a large number of industrial factories throughout the country.

The submarine mine was invented by Bushnell in 1777, improved by Fulton in 1812, further improved by Colt by the addition of the electric element in 1863, carried forward to a complete and practical system of mine defense by Gen. Henry L. Abbott, United States army, and since 1901 further perfected by the United States Coast Artillery corps in its use to the present efficient system of submarine defense of harbors, the planting and exploding of the mines at the right time and with precision be-

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

SUBMARINE PHOTOGRAPHY, a process of taking photographs under water discovered by Dr. L. Boutan, professor of zoology at the University of Paris. He has made successful experiments, to the depth of several hundred feet, on the coast of France and in the waters of the Mediterranean. Dr. Boutan in taking these photographs wears the regular diver's suit and extra heavy leaden shoes, so as to get a good foothold on the bottom of the sea. He uses the ordinary outfit of a photographer, with the exception that he has it all protected by water-proof coverings. He places his Leyden jars in a barrel which is surmounted by a bell glass provided with the necessary lamp. The latter is a spirit lamp to which is attached a receptacle for the magnesium powder connected with the usual pneumatic ball and tube. The photographs are taken by the instantaneous flash which follows the scattering of powdered magnesium into the flame. He has a branch tube connected with the pneumatic ball which forces a puff of air into the powder and carries it into the flame, exposing the lens at the moment of maximum light. The pictures taken at the bottom of the sea by this process show no material difference from those produced in the ordinary way by the instantaneous method, with one exception, that the negatives have a peculiarly soft tone. Since Dr. Boutan's accomplishment many others have succeeded in taking under-water pictures of great interest, which from time to time have ornamented pages of the magazines. One enterprising moving picture concern established a submarine outfit in a locality where sharks were common, and actually reproduced excellent views of a combat between a naked pearl diver and a shark, in which the intrepid diver neatly disposed of the great fish with a long dagger.

SUBMARINE SIGNALING. Submarine signaling is the art of producing sound waves in water and of transforming them into air waves so that they can be heard.

The art of submarine signaling has been directed entirely toward safeguarding lives and property at sea. Sound waves can be transmitted through water from a suitable source of sound and heard with well designed receiving apparatus at greater distances and with greater certainty than is possible through air with any sound-making device that has ever been produced. This fact gave the incentive to those who originally undertook the development of this art. Later, as the knowledge of submarine

signaling increased, it has become possible to determine with considerable accuracy, from a ship moving or at rest, the direction from which the sound is coming and even the distance between the ship and the sound-producing device. Moreover, the receiving devices have been so far perfected that it is not necessary that the source of sound should be made artificially. The receiving devices can now be made in such a way that the noises of invisible ships moving through the water can be heard and the position of the moving ship relative to the listener ascertained. With the latest forms of submarine signaling devices it is possible to send and receive telegraph messages transmitted by sound waves through the water. It must be appreciated that no wires connect the sending and receiving stations. Submarine signaling is wireless communication using compressional or sound waves in water as the means rather than the transverse ether waves used to-day in what is commonly called wireless transmission.

History.—It had been well known for nearly 75 years that sound waves were transmitted through water in the same manner as through air, but to greater distances and with greater velocity (velocity of sound waves in air about

FIG. 1.—Submarine Signaling.

1,040 feet per second; in sea water about 4,900 feet per second). A number of inventors prior to about 1900 had suggested or patented devices for making or detecting submarine sounds. No consistent or real progress was made until

in 1898 a group of investigators attacked the problem. These investigators and their successors, associated in the Submarine Signal Company, have carried the art to its present high degree of usefulness. A few of those who have made material contributions to the advancement of the art are Arthur J. Mundy, Elisha Gray, J. B. Millet, Lucian I. Blake, E. C. Wood and Reginald A. Fessenden.

Receiving Devices.—The earliest sound receiving device for use in water was employed by Colladon and Sturm in experiments made by them in Lake Geneva in 1823. The sound receiver was a large ear trumpet, the small end of which was placed in the observer's ear. The large end was closed with a thin plate and was placed under water. Modifications of this early form are in successful service to-day, but the receiver most commonly used to-day is an electrical current varying device similar in principle to the telephone transmitter generally used on land lines.

One of the problems in submarine signaling which has been most difficult of solution was to find a way by which the sound-receiving device should be responsive to the noises produced by the distant source and, at the same time, would be insensitive or non-responsive to the noises produced by the impact or movement of the surface waves of the water on the sides of a moving ship, and by the noises of the machinery within the ship. Innumerable means have been suggested for eliminating these foreign disturbing noises called "water noises." Success has been attained by the use of a properly designed microphone element or "button" mounted in a special form of watertight case, Fig. 1, and, when used on ship-board, by suspending the microphones in tanks, filled with water or other suitable fluid. These tanks are located within the ship below the water line and are so arranged that the fluid is in contact with the skin of the ship. It has been found that the sound waves from a distant source pass through the steel or iron skin of the ship with but little loss from reflection or absorption and, as a consequence, the sound waves from the distant source can be easily heard. Furthermore, by this arrangement the water noises are reduced to a minimum as the ship passes through the water with the least possible disturbance.

Electro-magnetic devices are less sensitive as receivers than microphones and are consequently less disturbed by the waves producing water noises. On account of this lack of sensitiveness they have not been as commonly used as the microphone. On the other hand, electro-magnetic devices have been made which can be mounted directly in the side of the ship, the diaphragm of the instrument replacing a portion of the skin of the ship which is cut away. Instruments of this kind arranged in this way have proved most efficient sound-receiving devices.

Sound-Producing Devices.—The earliest sound-producing device was a bell struck under water. Innumerable other means of producing sound have been suggested, tried and abandoned. Water sirens, subaqueous explosions and similar methods have never been brought to a degree of perfection which has made commercial use possible. The submarine bell has

remained up to the present time, with the exception of the Fessenden oscillator to be later described, the most serviceable form of submarine sound-producing device.

The development of a mechanism by means of which a submarine bell can be operated commercially in all weathers and for long periods of time has been very difficult. The problem has, however, been solved and several forms of submarine bells are now made to meet service requirements. One form, shown in Fig. 2, uses the movements of the surface waves to give the power required to strike the bell. In this form the bell and striking mechanism are supported at the requisite depth from a buoy or float. A wing, platform or "vane" is hinged to the sides of the bell case containing the striking mechanism, and is so counterbalanced that, as the bell case rises and falls with the waves, the differences in the movements of the bell case and vane cause a powerful spring within the bell case to be compressed and, when fully compressed, to be released. The released spring draws up the striker of the bell and causes a sharp blow to be struck. The bell mechanism is such that, whenever there is wave motion, the bell is operated at frequent intervals. Bells thus made can be kept in successful operation for considerable periods of time without attention and without any expense for the power consumed. The complete bell mechanism is so designed that corrosion, especially from sea water, is reduced to a minimum and, as all of the parts within the bell are immersed in oil, the wear upon the moving parts is small.

This form of submarine bell is the distinctive feature of the art of submarine signaling. The bell is supported from a buoy moored in places where there is no lightship or where it is practically impossible to obtain any other form of power with which to actuate the signaling device. The bell stroke is powerful enough to be heard at all times much farther than the uncertain signals that might be produced in the air by a mechanism operated by the energy derived from the motion of the ocean. The submarine bell can be used without requiring the attendance of an operator and in places where it is impossible to utilize wireless apparatus employing ether waves. Submarine bells of this type are to-day located at many points of danger on the coasts of most maritime countries and the number of bells in service is increasing.

Another form, shown in Fig. 3, of submarine bell has been designed for use from lightships. The blow of the striker upon the bell proper in these bells is produced by compressed air derived from an air compressor on the lightship. When signals are to be sent, the pneumatic bell is suspended from the side of the lightship and the compressed air is delivered to the bell through a hose. By a simple arrangement, the compressed air can be admitted by the normal operation of a key or automatically. Thus code signals, giving the number of the lighthouse station, can be sent out during the time the bell is required for operation.

Other forms of submarine bells are available for special conditions. Thus for service on buoys in rivers or other places where there is insufficient surface movement of the water

SUBMARINE SIGNALLING

Fig. 2 — Submarine Automatic Bell
Fig. 4 — Oscillator

Fig. 3 — Pneumatic Bell
Fig. 5 — Indicator Box

to operate the vanes of the bell of the type first described above, an electric bell is provided which is operated by electricity generated on shore and carried to the bell by a cable.

Another commercial form of sound-producing device for submarine work is the oscillator shown in Fig. 4, devised by Prof. Reginald A. Fessenden. The Fessenden oscillator is an electro-magnetic mechanism which is capable of producing sound waves in water of very large amplitude and, at the same time, can be controlled with ease. The Fessenden oscillator is shown in Fig. 4. A diagrammatic cross-sectional drawing of the oscillator is shown in Fig. 5.

FIG. 5.—Submarine Signaling.

The oscillator consists of a ring-shaped electro-magnet within which is a steel cylinder or core upon which is wound the requisite number of turns of wire. In the air gap between the core and the electro-magnet is a copper tube. The supports of the copper tube are two steel discs, rigidly clamped to a shaft, one end of which is firmly secured to a steel diaphragm, the outer face of which is in contact with the water when the oscillator is in use. The field magnet is energized by a direct current when the oscillator is in operation either for sending or receiving. When used for sending, an alternating current of approximately 540 cycles per second is made to pass through the core winding. This causes currents of electricity to be generated by induction in the copper tube with the result that great forces are produced which cause the tube to move back and forth at the frequency of the alternating current. The motion of the tube is transmitted to the diaphragm and to the water in contact with it. When the oscillator is used for receiving, the core winding is connected to telephone receivers. When incoming sound waves actuate the diaphragm, motion is imparted to the copper tube and currents of electricity are induced into the core winding. The currents in the telephone receivers, connected to the core winding, produce sounds of the same periodicity as those vibrating the diaphragm of the oscillator.

The Fessenden oscillator, when sending, produces a series of waves of constant frequency or pitch so long as an alternating current is passed through its core winding. By applying the alternating current to the oscillator for different lengths of time, it is possible to send series of waves of greater or less duration so that such series will correspond to the dots and dashes used in telegraphic communication.

Direction Finding.—It is customary when submarine signaling devices are used on ship-board to use at least two instruments and to so mount them that sound which reaches one instrument may be screened, under certain conditions, from the other. This is accomplished, in the simplest case, by mounting two small tanks on the ship's plates, inside the ship, one on each side toward the bow. The tanks are filled with water (or other fluid) and the sound-receiving devices are submerged in the water within the tanks. Each sound-receiving device is so arranged that it can be connected by means of a switch, with telephone receivers which can be held at the ears of a listener. When sound waves from a distant source reach a vessel equipped in this way, the sound waves agitate the sides of the vessel, and through the medium of the water in the tanks actuate the sound-receiving devices, thus varying the electric current and so producing similar sounds in telephone receivers. The sounds heard in the telephone receivers will be loudest when they are connected with the receiving device on the side of the vessel nearest to the source of sound. By turning the vessel until the sounds are the same from the receiving devices on both sides of the vessel, the direction of the source of sound can be ascertained, for the reason that when the sounds are equal the vessel must be pointing directly toward the source of sound. The so-called "indicator box," which is customarily employed on ships equipped with microphones supported in two tanks, one on the star-board and the other on the port side of a ship, is shown in Fig. 6. This device provides the means of connecting the telephone receivers with the microphones in either the port or star-board tank as may be desired.

While the above arrangement is that which has been most commonly used in direction finding, other methods are employed with satisfactory results which do not require the ship's course to be changed in order to obtain direction.

CLEMENT W. COUMBE,

Editorial Staff of The Americana.

SUBMARINE WARFARE. Of the many new instrumentalities of destruction employed during the recent World War the submarine torpedo boat proved the most effective. It differs from battleships and cruisers in that it operates for the most part beneath the surface of the ocean, it is slower of speed, frail of structure and possesses no facilities for the accommodation of crews and passengers found on the vessels which it sinks. Its inability, therefore, to comply with the well-established rule of international law governing prize destruction, which requires a naval commander before destroying a merchant vessel to provide for the safety of all persons on board, raised the question as to whether such craft were entitled to a special immunity from the rule governing prize destruction by cruisers and battleships, in short whether the submarine may be employed for the destruction of merchant vessels without violating the law of nations as well as the principles of humanity. Soon after the outbreak of the war the German naval forces for the most part were driven from the ocean

and compelled to take refuge in their home ports or in those of neutral countries. The Germans were, therefore, reduced to reliance upon submarine torpedo boats in their naval operations against the enemy and these were speedily built in large numbers and used on an extensive scale. By a decree of 4 Feb. 1915 the waters around the British Isles were declared to be a "war zone" within which, it was announced, all enemy merchant vessels would, if possible, be destroyed, notwithstanding the inability of the destroying submarines to provide for the safety of the crews and passengers found in such vessels. In pursuance of this decree scores of enemy merchant ships, including great ocean liners like the *Lusitania*, the *Falaba*, the *Arabic*, the *Persia* and many others, were torpedoed and sunk, sometimes without any warning at all or after warning which was insufficient to permit the persons on board to take to the lifeboats. In consequence of this mode of warfare large numbers of non-combatants, men, women and children, of neutral as well as of enemy nationality, lost their lives. A considerable number of neutral vessels were also sunk, the excuse alleged by Germany in most cases being mistake, which was an inevitable result of a method of naval warfare in which visit and search are never practised. In consequence of the protest of the American government and of its threat to hold the German government to a strict accountability for the loss of American lives, the German government in September 1915, while disclaiming all responsibility for the loss of more than a hundred American lives on the *Lusitania*, gave the American government assurance that in the future "liners would not be sunk without warning and without providing for the safety of the persons on board, unless the vessels attempted to escape or unless they offered resistance." The pledge, however, was not observed and on 5 October, in consequence of the American protest against the torpedoing of the *Arabic*, the German Ambassador informed the Secretary of State that orders had been given submarine commanders which were so stringent that the recurrence of "incidents" like the torpedoing of the *Arabic* would not again be possible. But notwithstanding these assurances, German and Austrian submarines continued to sink merchant vessels, enemy and neutral alike, without warning and without making provision for the safety of the innocent persons on board: among the most flagrant instances being the torpedoing of the Italian liner *Ancona* on 7 Nov. 1915, with the loss of more than 200 lives. It was true that this atrocity was committed by an Austrian submarine but it was understood in the United States that the German pledge bound the allies of Germany equally with herself and the Austrian government was fully aware of the American position in regard to the torpedoing of merchant vessels without making provision for the safety of their crews and passengers, and it was fully cognizant of the pledges given by Germany to refrain from the practice in the future. The action of the submarine commanders in continuing to fire upon the passengers while they were endeavoring to take to the lifeboats was characterized by the American government in a note to Austria as "wanton slaughter of defenceless non-combatants" and a demand was made upon

the Austrian government that the officer guilty of the act be punished and that an indemnity be promptly paid for the loss of American lives.

In February 1916 the German government announced that after 1 March its submarines would sink whenever possible and without warning all armed merchantmen, irrespective of whether they were armed for defensive or offensive purposes. The German government took the position that a merchant vessel had no right to carry guns, not even for the purpose of defense. Although the practice of carrying arms for defense against unlawful attacks had been followed by the merchant vessels of all nations for 200 years, the German government maintained that this practice had been introduced for the purpose of enabling them to defend themselves against pirates and later against privateers, but since piracy had disappeared and privateering had been abolished by the Declaration of Paris in 1856 the old rule no longer had any *raison d'être* and consequently the German government could not recognize it as binding. In short, according to the German contention, the rule was never intended to authorize merchant vessels to arm for the purpose of defense against the lawfully commissioned war vessels of belligerents. In fact not only armed merchantmen but also unarmed merchant vessels continued to be sunk, notwithstanding the pledges of September and October 1915. The torpedoing in April 1916 of the *Sussex*, an unarmed English Channel steamer, with 380 passengers on board, some 80 of whom lost their lives, came very near precipitating a crisis in the relations between the United States and Germany. The German government at first denied responsibility for the act, but when the proof produced removed all doubt as to this the German government finally acknowledged that the steamer had been torpedoed by a German submarine.

The President in an address to Congress, on 20 April, reviewed the history of German submarine warfare since its inauguration in July 1915 and informed Congress of the contents of a note which he had two days before dispatched to the German government and in which he denounced German methods of submarine warfare as contrary to both the law of nations and the sacred principles of humanity. The President concluded by saying that unless the "Imperial government should now immediately declare and effect an abandonment of its present methods of submarine warfare against passenger or freight carrying vessels, the government of the United States can have no choice but to sever diplomatic relations with the German Empire altogether." The German government replied that it had "imposed far reaching restraints in the use of the submarine," denied that the torpedoing of the *Sussex* was but one instance of a deliberate policy of indiscriminate destruction of merchant vessels of both enemy and neutral nationality, as the President had charged in his note; declared that it was ready to admit that there had been unavoidable errors and, again for the hundredth time, placed the responsibility upon Great Britain for having proclaimed a blockade against Germany for the purpose of starving the German nation, men, women and children alike, into submission. Notwithstanding all this, how-

ever, the German government in "the interest of the sacred principles of humanity" pledged itself that in the future unarmed ocean liners would not be torpedoed without warning provided they did not attempt to escape or offer resistance. This was the third time a pledge of this kind had been made to the American government. Like the others it was not lived up to and a considerable number of unarmed vessels were torpedoed and sunk by German submarines. As time passed, public opinion in Germany demanded a repudiation of the pledges given by the German government and the resumption of the policy of unrestricted submarine warfare. The tightening of the Anglo-French blockade and the growing feeling that this policy alone could save Germany from defeat intensified the popular demand. Finally, on 31 Jan. 1917, the German government threw off the mask and informed the American government that in consequence of a "new situation" having arisen which forced Germany to "new decisions" Germany must resume the liberty of action reserved in the *Sussex* pledge of 4 May 1916, and that, therefore, beginning on 1 Feb. 1917, German submarine commanders would no longer be bound by the previous assurances given to the American government. German submarines would, therefore, sink without warning all merchant vessels, *neutral as well as enemy*, encountered within a vast zone embracing more than a million square miles of the open seas (see WAR ZONES). The "new situation" referred to in the German note was the refusal of the Entente powers "owing to their lust of conquest," to enter into a discussion of peace terms with Germany and their avowed determination to starve the German people into submission in "brutal contempt of international law." The American government, it was added, knew the steps which Germany had taken to cause England and her allies "to return to the rules of international law and to respect the freedom of the seas" and the hope was expressed that it would "view the situation from the lofty heights of impartiality and assist on their part to prevent further misery and unavoidable sacrifice of human life." In consequence of this deliberate repudiation of its pledges the President recalled the American Ambassador from Berlin, handed the German Ambassador his passports (3 Feb. 1917) and broke off diplomatic relations with the German government.

The new policy thus announced by the German government was promptly and ruthlessly put into effect and large numbers of merchant vessels, neutral and belligerent alike, were torpedoed and sunk without warning. Neutral vessels laden with innocent cargoes even when consigned to their own governments, ships homeward bound in ballast, even hospital and Belgian relief ships proceeding on missions of mercy and philanthropy, in fact vessels of every nationality and mission were sunk as if they were pirate vessels. Down to 29 March 1917, 226 American lives had been lost since the outbreak of the war, in consequence of the torpedoing of merchant vessels by German submarines. In August 1917, the American consul, Mr. Frost, at Queenstown placed the total number of British lives, mostly non-combatants, lost in consequence of the German methods of submarine warfare at more than 10,000.

Turning now to a consideration of the lawfulness of this method of naval warfare we may state that a belligerent has an undoubted right to sink the merchant vessels of the enemy with certain exceptions (e.g., coast fishing vessels, hospital ships and vessels on philanthropic missions) in certain cases as where he cannot take the prize in to a home port for adjudication by a prize court, either because of imminent danger of recapture or for lack of a sufficient coal supply or because of his inability to spare a prize crew, and the like. But a long established customary rule of the law of nations requires that in such a case the commander must, before proceeding to the destruction, remove the passengers and crew of the vessel and provide for their safety, that is, he must take them aboard his own vessel or allow them ample time in which to take their own lifeboats. This humane rule is expressly laid down in one of The Hague Conventions, in the Declaration of London, and is even incorporated in article 116 of the German prize code as promulgated in August 1914. It is an equally established rule of the law of nations that the captor must visit and search the vessel, examine its papers and inspect its cargo, in order to satisfy himself of the nationality of the vessel and of its liability to destruction. The verification of these facts obviously cannot be made through the periscope of a submarine at a great distance. The German government frankly admitted that the obligation to provide for the safety of crews and passengers was binding upon the commanders of warships and cruisers but it denied that it was equally binding upon the commanders of submarines, for the reason that they were small craft, slow of speed, fragile in construction and were without facilities for accommodating crews and passengers found on the vessels which they destroy. By reason of their lack of speed it would often be impossible for them to give sufficient time for the crews and passengers to leave the ship and embark in lifeboats, without exposing the submarine to destruction by vessels of the enemy which might upon signal arrive on the scene before the torpedo had done its work. Moreover, it was argued, British merchant vessels were generally armed with guns which might be turned upon the attacking submarine with deadly effect in case it gave warning and an opportunity to the persons on board to leave the ship, before the torpedo was discharged. The rule in respect to providing for the safety of crews and passengers, the Germans argued, originated at a time when submarines had scarcely been dreamed of. Cruisers and battleships then were the principal craft employed for destroying enemy merchant vessels and they possessed facilities for accommodating crews and passengers or they could allow them sufficient time to take to the lifeboats without themselves being exposed to the danger of destruction. To require submarine commanders to observe this rule would in effect render the employment of the submarine for the destruction of prizes impossible, and this being the only available craft left to Germany for carrying on the war at sea she could not be expected to relinquish it. "New situations," said Professor Fleishmann of the University of Königsberg in an article on the "Lusitania Case," "necessitate new rules" and

the submarine being a new weapon is not bound to conform to the rules adopted long ago for the conduct of cruiser warfare. "Who," said Professor Zittelmann of the University of Bonn, "would have thought at the time the old rule regarding provision for the safety of crews and passengers, of the possibilities of submarine warfare." Had the use of submarines been anticipated, he says, "special rules governing their employment would have been devised" (see his chapter in a book entitled '*Deutschland und der Weltkrieg*,' 1916). The submarine, said Count Bernstorff in a memorandum laid before the Department of State on 8 March 1916, is "a new weapon, the use of which had never been regulated by international law." From this doubtful premise he drew the unwarranted conclusion that in using this weapon Germany "could not and did not violate any existing rule of law."

In the main, the German argument reduced itself to a claim of special immunity for submarines because of their peculiar build and consequent weakness. Since it is impossible to employ them in conformity with the long established rules governing prize destruction their commanders are relieved from the obligation to do so. In short, a prohibited method of warfare becomes legitimate whenever a new instrument for doing it is invented—that is, whenever an immediate belligerent interest would be subserved by the employment of an instrument which cannot be employed in conformity with the existing rule of law, the rule may be overridden and the interest allowed to prevail. This argument is specious; it ignores the fundamental fact that the rule of international law which requires naval commanders to spare the lives of innocent non-combatants on the merchant vessels which they destroy was adopted in the interest of humanity and was intended to govern prize destruction by any and all types of vessels which then existed or which might be invented in the future. To argue that a submarine commander may drown unoffending non-combatants but that the commander of a cruiser cannot is preposterous. The employment of new instruments and agencies of destruction must be adjusted to the requirements of the law, not the law to the instrument; it cannot be admitted that the invention of a new weapon may serve to repeal the law of nations and of humanity. The German defense harmonizes well with their theory that "whatever is effective and whatever tends to shorten the war is legitimate"; in its final analysis it amounts to a claim that a single belligerent may at will change the law of the sea to meet his own immediate necessities. The United States Supreme Court in the case of the *Scotia* laid down a principle of international law which has never before been contested that "the law of the sea is universal and cannot be changed by a single nation." Germany, therefore, had no right to repudiate a long established rule which by common agreement had come to be a part of international law. It will readily be admitted that the introduction of the submarine will necessitate certain modifications of international law, those governing blockade, for example, but it cannot be admitted that the invention of a new instrument of destruction can alter what the President of the United States called "those rules of fairness, reason,

justice and humanity which all modern opinion regards as imperative."

The Germans claim, in fact, that in many instances in which their submarines destroyed merchant vessels they saved the persons on board *whenever possible*. But there are almost no recorded instances in which crews or passengers were taken aboard the submarine, for the good reason that submarines have no accommodations for any but their own crews. The Germans likewise claim that wherever possible they allowed sufficient time for the crews and passengers to leave the ship and take to the life boats, but the instances in which this was not done are so numerous that it may be said that the contrary practice was rather the rule. In many cases where warning was given before the torpedo was discharged, the period of time allowed, sometimes not more than 10 minutes, was wholly inadequate, and instances were common in which huge ocean liners sank while the passengers were endeavoring to leave the ship. Incredible as it may seem also, instances are not lacking (e.g., the *Ancona*) in which the crews and passengers were deliberately shelled while taking to the boats. Even when ample time was allowed the passengers to leave the ship it was only a technical compliance with the rule requiring naval commanders to provide for the safety of the persons on board, for they were set adrift in small boats often hundreds of miles from land, sometimes in mid-winter, without food or drinking water and left to drift at sea for days, to suffer the tortures of thirst and hunger, to die of starvation or exposure to cold or to be washed overboard by rough seas and to drown while struggling to save themselves. The German government readily admitted (in a note of 29 Nov. 1915, relative to the sinking of the *Frye*) that this procedure was not a sufficient compliance with the spirit of the rule nor in accord with the assurances which were given the government of the United States that the crews and passengers of ships sunk by German submarines would not be exposed to danger in this fashion.

Few chapters in the history of the Great War reveal German militarism in a worse light than this cruel war against unoffending non-combatants who were in most instances peacefully navigating the seas for the freedom of which the German Government pretended to be fighting. For sheer ruthlessness and barbarity there is nothing comparable to it in any other modern war. German methods of submarine warfare have frequently been characterized as piratical. Technically, of course, their submarines were not pirates, since their commanders bore commissions from a belligerent government, but they might with reason be considered as pirates within the meaning of the old rule which defined pirates as *hostes humani generis*. Naturally few reputable authorities on international law outside Germany have been found to defend such methods of warfare, and even in Germany and Austria they have been denounced as barbarous by many persons, notably by leaders of the Social Democratic party. It is difficult to reconcile the conduct of the German submarine commanders with the utterance of Germany's great diplomat, Marschall von Bieberstein, who at the second Hague Con-

ference said: "The officers of the German Navy, I loudly proclaim it, will always fulfill in the strictest fashion the duties which emanate from the unwritten law of humanity and civilization. As to the sentiments of humanity and civilization, I cannot admit that there is any government or country which is superior in those sentiments to that which I have the honor to represent."

Professor of Political Science in the University of Illinois.

SUBMARINES: THEIR HISTORY, DEVELOPMENT AND EQUIPMENT.

The aerial flight of the bird and the subaqueous navigation of the fish were always wished-for and dreamed-of activities of human ambition. Science achieved both performances between the years 1900 and 1906, when the actions of the denizens of the air and sea were brought within the practice of mankind by the airplane and submarine. Protracted life and motion within each of the elements has in the last Great War been such a prominent and methodical part of warfare that they are already commonplace to us. But while the performance of the dirigible and heavier-than-air machines has been visible by millions of our populace, the invisibility and secrecy surrounding the submarine has been maintained, few ever seeing the submersible in action and still fewer having been allowed access to her internal economy. A fairly lengthy description of the "secrets" of the submarine should be of peculiar interest to readers.

History.—A Dutchman, Cornelis van Dribel, in 1624 invented a successful submarine rowboat, and King James of England was passenger on one in a subaqueous voyage on the river Thames. Contemporaries describe the vessel as an ordinary large rowboat decked over with stout, well-greased leather. About 1652 Le Son, a Frenchman, built a wooden submarine (known as the "Rotterdam Boat") 72 feet long, 12 feet high, with 8 feet beam. It had sharply tapering ends and sloping sides (for defense against projectiles) and iron-tipped legs for resting on the bed of rivers or bottom of the sea. Midships a paddle-wheel propelled the vessel. In 1747 Symons built a submarine decked rowboat having leather bottles projecting through her bottom; when filled they submerged the boat and by forcing out the water with a lever and fastening the necks the boat rose to the surface. An English mechanic named Day

built a boat he could submerge 30 feet, remaining 24 hours under water in it. He tried the same performance with a 50-ton sloop on a bet in Plymouth Harbor, but the boat failed to rise and he was drowned. In 1776 David Bushnell, a native of Connecticut, invented his submarine, or rather submersible, boat *Turtle*, so christened because its sides were shaped like the shell of a turtle. When submerged the head of its single passenger remained above the water in a conning tower while he propelled the boat with a bladed tractor forward. Lead ballast kept her submerged. From the rear-end of this lense-shaped hull projected an arm-steered rudder. Sergt. Ezra Lee operated the craft and when the British fleet entered New York Harbor to capture Manhattan Island Lee tried to attach a mine to one of the men-of-war but failed after repeated attempts, barely escaping capture. In 1797 Robert Fulton tried vainly in Paris to interest the French government in his plans for a submarine even after he had built a model and an appointed commission had given a favorable report; he next appealed to the government of Holland. In 1800, however, First Consul Napoleon advanced 10,000 francs for Fulton to build a submarine, which was launched and christened *Nautilus*. It was constructed of copper plates on iron ribs and fish-shaped, 21 feet 3 inches long, 6 feet 3 inches diameter at the widest part. Stability was gained by a heavy keel, above which were water ballast tanks. It was driven by a two-bladed propeller geared to a hand wheel. A dome formed the conning tower. Horizontal planes guided her downwards. Above the surface a sail unfurled itself fanwise on a hinged mast upon pulling a rope. Fulton and another remained submerged, on the trial, 20 minutes in the Seine, extending the period to six hours' submersion later at Brest, aided by a tank of compressed air. He blew up an old ship by attaching an explosive shell to her bottom to prove the practicability of the offensive craft. Failure, however, to injure the English fleet as a proof caused the French government to refuse further negotiations. Fulton went to England and interested Prime Minister Pitt and he successfully blew up the *Dorothea* with a time bomb attached to her during his submersion; but within a week Nelson at Trafalgar so injured the morale of the French fleet that England's danger from sea attack was gone and Fulton returned to America, where he again failed to gain government recognition of the merits of his submarine. The Confederate torpedo boat *David*, which could not actually submerge but had to keep her funnel and pilot-house above water, attacked and exploded a spar-torpedo against the iron-plate protected hull of the U.S.S. *New Ironsides* in Charleston Harbor, October 1863, but did little damage. The Confederate *Hundley* was a true diving craft with ballast tanks, diving planes and driven by hand power. Each of her five trial trips met with serious accidents and loss of some or all her crew. General Beauregard was still able to get volunteers for another trip and determined this time to make it a practical test against the Northern blockade fleet. On 17 Feb. 1864 the *Hundley* blew up the U.S.S. *Housatonic*, a new corvette of 13 guns, in Charleston Harbor, with a spar-torpedo which struck her and ex-

ploded her magazine. But the *Hundley* went down with her victim. And this was the first success of a submarine's action with a warship and the only one till the late World War. The *Stromboli* and *Spuyten Duyvil*, constructed by the United States government, submerged their hulls only, leaving the upper works (conning tower, ventilators, etc.) above the surface. With the invention by Whitehead (1864) of the fish torpedo and automatic propulsion by compressed air, the dangers of self-immolation of the aggressors in torpedo attack disappeared. (See TORPEDO). William Bauer, a Bavarian, now invented a submarine craft but it was refused by the governments. Halstead's *Intelligent Whale* (1864-65), quite similar to the *Nautilus*, was supposed to allow a member of its crew (a diver) to emerge and place a torpedo under a ship; experiment ended in failure. In 1863, Captain Bourgois and M. Brun, Frenchmen, built the steel submarine *Plongeur*, 146 feet long, equipped with an 80 horse-power compressed-air engine; she behaved too unsteadily, submerged deeply and her engines had insufficient capacity. The Frenchman Olivier Riou (1861) failed in his trial of electricity as the motive power; then his compatriot, Admiral Aube (1886), took up the electric idea and built a small experimental vessel, the *Gymnote*, on lines laid down by Dupuy de Lôme, who had recently died; it was 55 feet long and had 564 battery cells developing 55 horse power. Showing good points, the French government built the larger *Gustave Zédé*, on similar lines but advanced principles. She failed in every respect at first, but after years of experiment and alteration became practical. From 1886 to 1901 the French government was so enthusiastic in adopting the submarine as an arm of the fleet that she built 29, all electric driven. M. Goubel, a Frenchman, experimented with two small electric submarines at this time but they were failures. In 1878 the Rev. G. W. Garrett, an Englishman, built a submarine which he christened *Resurgam* ("I shall Rise"). Advancing in his calculations he built a second with a steam engine. On submersion the smoke-stack was closed with a sliding panel and the furnace was shut up tight and the engine under water was run by steam from the reserve tank of hot water. Thorsten Nordenfeldt, Swedish engineer and inventor of the famous gun bearing his name, took up and improved the Garrett system so that his boat ran for 14 miles submerged. He next got patents for his vertical propeller device which drove the craft deep under the surface. After tests (1886) Greece purchased his first craft and he built larger submarines (*Nordenfeldt II* and *Nordenfeldt III*), which Turkey acquired. The first of the latter introduced the novelty of a torpedo-tube in the bow to discharge Whitehead torpedoes. They were shipped to Turkey in parts and one was assembled in Constantinople for tests and acted well on the surface, but under water, with every movement of her crew, she lost her level keel and dived nose down or tail first, whichever part her crew worked. Firing a torpedo she lost her balance badly, but seasawed till her crew got her safely to the surface. As no other crew could be found to take the risk, she rusted in dock and when the British attacked the Dardanelles she could take no

part in the defense. The Russian Drzewiecki and the Spaniard Peral invented a foot-driven propeller submarine which proved useless. A strange submarine craft indeed was that projected by the Russian Apostoloff, whose hull was armed with great "threads" forming a gigantic screw by means of which, the hull revolving, this great propeller would, the inventor claimed, cross the Atlantic at 111 knots an hour. His submerged hull was to have a large cabin suspended by davits above the water. John P. Holland, an Irishman, in 1875 built a 16-foot long, two feet diameter, cigar-shaped submarine vessel in New Jersey (*Holland No. 1*), which carried a torpedo that was to be attached to the bottom of the enemy ship and then exploded like the plan of Bushnell with his *Turtle*. The craft was divided into an air-chamber fore and aft and two compartments amidships, in one of the latter of which the operator reclined while working pedals with his feet to turn a propeller in the stern. It enabled Holland to practice navigation beneath the Passaic River and neighboring waters. *Holland No. 2* was launched in 1877 and stuck in the mud. She was furnished with an outer hull for water ballast and was driven by a four horse-power petroleum engine. A few experiments proved to both inventor and spectators that she was a failure and he sunk her after salvaging the engine. He persuaded the Fenian Brotherhood to pay for the construction of two of his submarines with a view to attacking English men-of-war, but they do not appear ever to have shown activity. Holland constructed five more submarines without profit; but in 1893 Congress made an appropriation for constructing an experimental submarine and invited bids. Holland won against his competitors and in 1897 his *Plunger* was launched but had so many evident defects she was never finished. *Holland No. 8* followed and failed, but *Holland No. 9* was built and was the first successful submarine from actual practical viewpoints. She was launched in 1898 and was 53 feet 10 inches long, 10 feet 7 inches deep and porpoise-shape. In 1900 she was placed in commission by the United States navy. Her power was conveyed on the surface by a 50-horse-power gasoline motor and by electric storage batteries when submerged and the combination of the two methods of propulsion was the great Holland achievement. Upon filling her water tanks she sank till flush with the water's surface, then two horizontal rudders steered her to a depth of 28 feet in five seconds. As periscopes had not been perfected, she had to rise and dip like a porpoise to get an air-glimpse and aim. Repeated tests produced such satisfaction with Admiral Dewey and his fellow-officers that the United States government ordered six submarines of this type and in 1901 the British Admiralty ordered five. The race was on and all the navies ordered *Hollands* or paid royalties to the inventor's patent to build larger or improved craft. But the British Admiralty acquired the master patents, making a purchase of all rights for Great Britain, and has built up England's fleet on Holland lines, making, of course, many changes. The next *Holland* submarines were built for seagoing purposes and were constructed for the United States navy, having 122 tons displacement, 160 horse-

power gasoline engines for surface and 70 horse-power electric for submersion, making, respectively, eight and one-half and seven knots with 300 miles radius awash. These were termed the *Adder* class, after which came the *Viper* class, somewhat larger, and the *Octopus*. The latter was furnished with twin screws and had 273 tons displacement submerged, surface speed 11 knots, produced by internal combustion engine of 500 horse power and 10 knots submerged, developed by electricity. Simon Lake, a Baltimore citizen, built a triangular box-shaped submarine craft, which he named *Argonaut Junior*, that could sink to the bottom of a river or lake and permit a passenger to emerge through the bottom by an air-lock filled with compressed air. The passenger, equipped with a diving suit, could search the bottom of the river. The strange craft was mounted on three wheels, the front pair was rotated by hand gear, the rear one did the steering. In 1897 Lake built his *Argonaut*, having cigar-shaped hull 36 feet long, on similar principles, but with a 30 horse-power gasoline engine, the fresh air being supplied through a hose connected with a float on the water's surface (later changed to two tubular masts). For sinking, *The Argonaut* relied on two anchor weights of over 1,000 pounds attached to cables and raised and lowered by a drum on the vessel. On lowering the weights to the bed of the river, then letting in water to ballast compartments, the weight cables were hauled in till the vessel rested on her wheels at the bottom of the water, when the weights were hauled into pockets in the keel. In 1898, *The Argonaut* traveled from Norfolk to New York under her own power. To fulfil the prophetic vision of Jules Verne's *Nautilus*, *The Argonaut* covered over 1,000 miles submerged. She was lengthened in New York and a superstructure of ship form was built over her, making her a safe sea-going submarine riding waves easily. *The Narval*, conceived in 1899 by M. Labeuf, was launched in France with its double hull, the outer shell perforated. She used steam on the surface and storage batteries beneath, but absolute silence has been maintained as to advances in French submarines. In 1906, Lake's *Protector* was built and sent to Russia equipped to run along the bottom of the water and cut through enemy nets, avoid mines, rocks and sandbars. Lake was consulted by the German firm of Krupps, who, he says, agreed to employ him as adviser in the building "Lake type" boats and share the profits with him; after parting with his plans and specifications he says the Krupps refused to sign the agreement and used his plans on the submarines they built during the World War.

Until recent years naval authorities divided war submarines into two classes: *Coast defense* type of from 300 to 700 tons surface displacement and *cruising* type of from 800 tons up with radius of 3,000 miles or more.

Submarine Construction and Equipment.—As may be supposed the apparatus and mechanism for such a complex condition of warfare must be very elaborate and complicated. The submarine's internal bewildering labyrinth of pipes, valves, gears, wheels, cylinders, etc., crowding the confined space is the wonder of those few visitors who are allowed an inspection of their interior workings. We will give

a short review of the subject as described by such experts as M. F. Hays and others.

Hulls.—Submarines are built with double and single hulls. The latter have to be of considerable strength to resist the pressure when submerging deeply, necessitating a circular or nearly circular cross section. They were of so-called *spindle* shape, both ends tapering to reduce the resistance in motion, but to obtain better sea-going qualities the bow and stern have been modified in recent construction. The Holland type has single and double hulls; the Labeuf type has an inner hull cylindrical with flat ends; this is enclosed entirely in an outer hull pointed at each end to reduce resistance in motion. The latter are used by the French, Austrian and German (Krupp-Germania) navies. Another type has single hull reinforced in parts by an outer construction as employed by the Italian, Portuguese and Brazilian navies and designed by Maj. Cesare Laurenti of the *Fabbrica Italiana Automobil Torino (Fiat)*, while the Dutch and Danish navies have used a composite hull designed by M. F. Hay. Other types have, of course, been developed.

Engines.—Steam soon had to give way to high-speed internal combustion engines. The first "Hollands" built for the British navy were fitted with four-cylinder vertical engines. Next came 16-cylinder Wolseley horizontal motors with 550 horse power; later, with increased dimensions they arrived at 850 horse power, giving 16 knots surface speed. The remaining defect was the noxious gas from the petrol or gasoline fuel, sickly as well as dangerously explosive, not to mention carburetor objection so well-known to aviators. Then came the new Diesel motor invention using heavy (crude) oils and all the above troubles were wiped out when the early slow-speed defects were overcome. England used her first Diesel motor on submarine *D1* in 1907, developing 1,200 horse power. Its simplicity of operation, though complicated in mechanism, makes the Diesel engine (see INTERNAL COMBUSTION ENGINE) perfect for surface propulsion, its low cost of running also being much in its favor. A development of 5,000 horse power by 1915 was a great advance over two- and four-cycle engines. The Fiat firm advanced the high-speed Diesel greatly and Britain gradually took up the work; all boats since and including the E and F class have Diesel engines. Diesel engines have been used on all United States Holland boats for the last ten years. The driving power for under-water activity remains electricity, derived from batteries placed below the main floor of the machinery space. On later types of submarines, batteries are placed in a lead-lined compartment to prevent corrosion of hull by sulphuric acid fumes. But in recent types the Diesel engine charges the batteries and does away with these dangers. Krupps of Kiel and M.A.N. of Nuremberg developed, at the German government's expense, engines best adapted for their 900 tons submerged displacement submarines and (1915) two Diesels of about 900 to 950 brake horse power were installed on each and found to act admirably. Many other navies were supplied with them. The M.A.N. Diesels constructed at Augsburg four-cycle, 800 horse power and the Nuremberg M.A.N. two-cycle motors of 900 horse power. The Diesel engines of the British sub-

marines were built by the Vickers company and are four-cycle; those for E class developed 800 horse power in eight cylinders. The Fiat two-cycle 1,300 horse-power motor has been used by both Italian and British submarines, having six cylinders and 400 revolutions per minute. The Sulzer Brothers (Swiss) two-cycle reversible 600 horse power were used at that time (1915) by the United States and Japan. The Polar (Stockholm, Sweden) four-cycle motor was used by the Swedish navy.

Tank System.—The submerging from surface to underwater conditions is brought about by reducing the vessel's buoyancy by means of filling her tanks with seawater. The tanks of the single hull construction are, of course, built inside the vessel, whereas in the case of double hulls the intervening space between the hulls is the tank space. But the disposition and dimensions of these water-ballast tanks is one of the most important problems of submarine building. The safety as well as the efficiency of the vessel hinges entirely on the absolutely correct calculations made in designing the submarine. The history of failures and accidents is generally that of faulty tank distribution. With full tanks the vessel must lie on a level keel under the water. The tankage space has to be divided into a dozen or more compartments so that each unit shall be strictly self-contained in its action and each tank must be completely filled before submerging. This set of "main ballast tanks" has to reduce the buoyancy, leaving only 25 per cent. In about the middle of the ship's length is another tank known as the "central," "midship," "buoyancy" or "auxiliary" tank; this must *never* be completely filled after submerging. Next come the "trimming" tanks located fore and aft, used in maintaining the vessel on an even keel when getting ready to submerge. All submarines have the above tanks. To them are added, generally, "compensating" tanks, each to compensate for the consumption used up in operating. Thus we have fresh water, the torpedo, the fuel and the lubricating oil compensation tanks; all needed to maintain the original weight. A "safety" tank is installed in some submersibles for use in case of emergency (accidents, etc.); this is quickly emptied by air pressure. But in recent constructions each tank is made capable of being emptied by air pressure, making the special one unnecessary. Emptying the tanks quickly brings the submarine speedily to the surface in case of accident.

Steering Gear.—Steering can be performed on top of the conning tower, in the conning tower or in the "central station," properly called central operating compartment. Small submarines are steered by hand power, the larger by electricity, but in the latter case, as on other ships, emergency handgear is provided for use in case of electric trouble. An indicator alongside the steering gear shows the rudder's position and direction is found by repeating compass when a gyroscopic master compass is installed, otherwise the steering station has its own compass if magnetic or has an image reflected from the master compass.

Diving Gear.—The diving "hydroplanes" (horizontal rudders) are operated similarly to the rudder. When the diving rudders are at bow and stern there are generally two hand wheels and the operators receive each instruc-

tion from the first officer. In sight of operators are depth gauges (the depth attained is read on a pressure diagram) and two indicators display position of rudder and inclination of the vessel respectively. The submarine under ordinary conditions cannot remain below water unless under way, at least slowly, but when it is necessary to stay in one spot for a period there is available the "statical diving gear" which admits and ejects a small amount of water into or from the central ballast tank as the vessel shows inclination to rise or sink from her position.

Air System.—The need of air on board is for many purposes besides breathing. Air is installed in seamless steel flasks compressed 2,500 pounds pressure per square inch and others at 1,000 pounds. After reduction of the pressure by valves the first kind is used for blowing out the water tanks, for charging the torpedoes' air chambers, for charging the flasks for firing the torpedoes, for refreshing the air breathed by the crew and for blowing the whistle; the latter pressure air is required for starting the Diesel engines.

Water Piping System.—Several pumps driven by electricity are generally installed to give a duplicate system of piping to each tank and they are so distributed as to preclude all pumps being thrown out of commission in an accident.

Refrigerating System.—This is installed for campaigns in tropical waters.

Heating System.—This is installed for campaigns in frigid waters as the North Sea, north Atlantic, etc.

Anchor Gear.—In great storms on certain occasions anchoring is an urgent need. In spite of the difficulties attending the invention of a practical device in recent years most large submarines are equipped with two located on bow and capable of use while submerged, operated, of course, from the inside, but for fear of inability to disengage the anchor when let down, a method had to be devised to cut the cable or slip it.

Navigating Appliances.—Under submerged conditions a gyroscopic compass set is, of recent years, considered among the necessities. It consists of the master compass in the central station and three repeating compasses magnetically operated by the former and located at the steering stations. A device for depth sounding is also necessary as the submarine often runs in uncharted waters. The engine-room telegraph, speaking tubes, ship-lights, etc., are those common to ordinary ships.

Air Regenerating System.—A few navies supply each submarine compartment with a vessel containing a chemical to absorb carbon-dioxide and several flasks of compressed oxygen for emergencies when the vessel has to stay submerged over 24 hours and the air becomes vitiated.

External Fittings.—All submarines except the Laurenti type carry a walking platform constructed with light metal plates and which also answers as a smooth surfaced covering to the anchor gear, entrance and escape hatches, lifting eyes, engine exhaust pipes and other projections that would afford resistance in navigation. The conning tower, located midships, has been greatly increased in dimensions in recent years to afford space for navigating the

vessel on the surface when stormy weather forbids using the bridge. Some of the German conning towers reach nine feet above the upper deck. In the German boats one of the periscopes enters the conning tower and navigation in such is carried on in the conning tower when slightly submerged and, therefore, has to be sufficiently roomy to hold two or three men. In the walls of the conning tower are eight or so sighting ports fitted with plate glass about an inch thick to resist the great pressure; bronze port covers are also provided to aid in withstanding the pressure when very deeply submerged or when the glass gets broken. A portable railing is provided for use around the superstructure deck and is removed on submerging. Exposed to view outside the hull are a towing hook for use when disabled and abaft the forward bow are the diving rudders, some of which fold up into a pocket leaving the space occupied flush and as they are only in use when submerged they are operated from inside the hull. On the deck is the bell for signaling under water. (See SUBMARINE SIGNALING). The perpendicular pipes that project from the wave-breaker are ventilators communicating with the living quarters and engines. Large submarines lately carry a folding-boat that is stowed in the superstructure.

Living Arrangements.—On the larger or sea-going boats the average of three officers and 20 men have three separate cabins fitted up rather similarly to the quarters on a steamship, with plenty of locker accommodation and steam-heated in cold weather. Steel work is encased in compressed cork to absorb moisture.

- The cook's galley is equipped with electric range, oven and hot-water reservoir. Coffee and soup are kept heated electrically in urns.

Armament.—Most navies equip their submarines with four torpedo tubes, two on the bow and two astern; others carry an additional two in the superstructure; the latter are of fixed or revolving type. Some British submarines have fixed port and starboard broadside tubes in the interior of the boat. The number of torpedoes carried varies from two per tube to whatever the larger space of the big vessels permit. Both ends of the torpedo tube are covered by watertight caps or shutters each opened and closed by hand. To load a tube the inside cap is opened, leaving the outside closed and the projectile is placed in the tube, the inside cover being at once closed and the open spaces at head and tail of the cigar-shaped torpedo is filled with water by pumping or blowing water from an internal tank specially fitted for the purpose. Next the outer shutter is opened and the projectile is discharged by compressed air, released from a tank and entering behind the torpedo by electric gear operating a large valve. The boat's commander generally performs this latter operation. During the torpedo's egress mechanism in the tube pulls a lever that starts the propelling machinery of the torpedo as it leaves the tube on its deadly mission. Another weapon of the submarine is its one or two three-inch rapid-fire guns used as defense against airplanes, dirigibles and small craft. In submerging the gun is housed in the superstructure aided by its hinged mount. To render the mount more rigid the later German submarines have eliminated the hinge and on submersion

leave the gun projecting, after removing the breach-block and sighting telescope. To reduce propulsion resistance when submerged the gun is enclosed in a "breakdown" casing of sheet metal. During the World War cannon have been added to armament, the calibre growing ever with the capacity of the enlarged boat. (See notice, end of article, on the very latest structures).

Periscopes and Range Finding.—The eyes of the submerged craft—the periscope—in its more recently developed form consists of an arrangement of prisms within a vertical tube (see PERISCOPE) adjusted to an eye-piece similar to a marine telescope. Usually submarines have at least two periscopes to provide for loss, besides permitting commander and the steersman to be using one each simultaneously. The periscope tube has about six inches diameter and 18 to 20 feet length above the superstructure. The more recently constructed periscopes have on the upper end a reduced diameter of from two to three inches for the length of five or six feet. This has the effect of reducing the "periscope wave" left in its wake which makes itself more visible to the enemy than the projecting tube. The remaining instrument needful to correctly aiming the torpedo is a range-finding device; for this purpose there are several inventions, space for the description of which in this article is lacking. The dangers attendant on the operation of the submarine have given rise to numerous inventions for their prevention and cure. One of the most interesting is the "safety keel" used in European navies; it consists of a flat, hollow keel filled with lead and has a depth of about 12 inches and about 24 inches width. This is fastened to the hull in such a way as to permit quick releasing in emergency and the reduced tonnage quickly brings the vessel to the surface.

A good example of strictly recent submarine construction is the Holland type, United States submarine *Schley*, built in 1917. It is 263 feet long, displaces 1,453 tons submerged, has surface speed of 20 knots, submerged speed 11½ knots. The hull is divided longitudinally into nine watertight compartments. There are four torpedo tubes in the bow, two port and two starboard; water-ballast tanks are also located here for their discharge. There are also two deck torpedo tubes besides those (four) in the bow. Aft of this is the torpedo compartment. The officers' compartment comes next and the crew's quarters, with storage batteries below deck, is aft of the officers' quarters. Next comes a smaller compartment, the upper part of which contains the wireless operator's room, while the lower half is devoted to cold storage. Next, at about midlength of the vessel comes the central operating compartment with conning tower and the bridge above. The *Schley* has three periscopes, two running into the operating room, the third leading to the conning tower. To the rear of this is another crew's quarters and storage batteries beneath its floor. Next comes the engine-room with its two 12-cylinder engines, capable of driving the vessel at 20 knots on the surface. The next compartment contains the electric motors, one attached to each shaft, together with other auxiliary machinery. Water ballast fills the last compartment. The torpedo armament consists of four fixed tubes in the

bow; and two others on a revolvable mount, which are carried above the main hull, and within the false superstructure.

During the progress of the World War wonderful stories appeared in print of the great advances being made by Germany in submarine construction and the immense size of her latest craft. The British navy had been well posted because of steady capture of enemy submarines and their consequent examination. But the officers were silent and the public was unenlightened. Captain Persius, Germany's naval critic, gave out the following figures concerning the German submarine fleet: In 1917 Germany built 83 and had 66 destroyed; in April of that year she had 126 submarines; in October 146. In February 1918 she had 136 and in June 113. England's 1917 War Cabinet declared the German submarine had a surface speed of 18 and 10 or 11 knots submerged. It

later). All details are not given out but we read of four of these enemy boats: "The best of these were 'tuned up' for special trial" and a special trial board appointed. The German boat tried was *U-III*, built at Germania Yard, Kiel, 1918, and *S-3*, a submarine designed by the United States Navy Department and commissioned in 1918. They both belong to the 800-ton class with the following measurements:

	<i>U-III.</i>	<i>S-3.</i>
Length.....	235 feet	231 feet
Beam.....	21 feet	21.5 feet
Draft.....	12.5 feet	12.5 feet

The report reads: "In the trials the maximum surface speed of the *U-III* was 13.8 knots, while the *S-3* made 14.7 knots. The submerged speed of *U-III* was 7.8 knots, while *S-3* made 12.4—a remarkable difference in favor of *S-3*. The radius of action of the two boats is

[Longitudinal Section of Submarine.

carried 15 to 20 torpedoes and was able to travel 100 miles submerged, remaining completely submerged up to 48 hours. On fairly reliable information we learn that England at the outbreak of war had about 80 submarines, built about 130 more and lost about 50 during the conflict. The British experts were surprised, when the Germans brought in their submarines according to the terms of the armistice, how little they had to learn from them. By 1917 both England and the United States were building submarines of 1,500 to 2,000 tons. And now, it is claimed, Britain has in her *M-1* a 1,700-ton submarine carrying a 12-inch gun (six-inch guns were the big calibre during the war). She has two tubes and an anti-aircraft gun. It is also said that the British have steam-driven 2,700-ton submarines with surface speed of 23 to 25 knots. In September 1916 was published an interesting report of the United States navy making comparative tests of American submarines alongside the German (examples of which arrived here

also in favor of *S-3*, despite all the furore that was created by the advent of the U-boats on the American coast during the war. *U-III* can cruise 8,500 miles at eight knots, while *S-3* can cover 10,000 miles at 11 knots. The submerged cruising radius shows an equal preponderance in favor of *S-3*. Both can carry 12 torpedoes. *U-III* mounts two four-inch guns, one forward, one aft, while *S-3* mounts one gun forward, this practice of one gun on a submarine being standard practice in the United States navy." Living accommodations are far inferior on the German boat, and, according to the report, unnecessarily so. As to seaworthiness the American is the better, "decks drier, her bridge less subject to green seas, and her general behavior in a sea-way superior." Diving capabilities differed little, but slightly in favor of the *S-3*. The latest word in United States undersea boat construction is the *AA-2* built September 1919 from designs of the Electric Boat Company and declared to be the fastest Diesel-engined boat afloat. She has a cruising radius of about 7,000

miles, is 268 feet long and her surface speed is expected to develop 20 knots an hour, 13 knots submerged.

Bibliography.—Bishop, F., 'The Story of the Submarine' (New York 1916); Hay, M. F., 'Secrets of the Submarine' (New York 1917); Lake, Simon, 'The Submarine in War and Peace' (Philadelphia 1918); Newbolt, Sir Henry, 'Submarines and Anti-Submarines' (New York 1919); Talbot, 'Submarines: their Mechanism and Operation' (London 1915).

SUBPŒNA, sŭb- or sŭ-pe'na, ~~in~~ *law*, a writ directed to a witness, commanding him to appear at the court to testify what he knows in the case therein described, pending in the court. Should the court wish to examine any books or papers connected with the case in possession of the witness, a clause is inserted in the writ instructing him to bring them with him. An action of damages lies against the party disobeying this writ, unless he has a good legal excuse; but the subpœna must have been served a sufficient time beforehand to enable him to arrange his affairs. See **WITNESS**.

SUBSCRIPTION. From the Latin *sub*, under, and *scribo*, I write. In the common vernacular this term defines the placing of a signature to any written or printed statement. In the law it applies to the signing of one's name to an engagement, or is the attestation of a witness by so writing his name; the illiterate or blind person, however, is permitted to make his mark as a sufficient subscription. It most commonly applies to a person making an agreement over his signature to furnish certain moneys for a particular purpose, as a subscription for a book, or to a charitable institution, etc. The extent to which subscriptions, made voluntarily, for charitable objects are binding still remains a legal problem. In subscribing, "agreeably to the statute and by-laws of a chartered company," the party acquires a right to his shares, which is sufficient consideration to make the subscription binding on his part. Subscriptions to a contemplated corporation may be enforced when the corporation is formed. "The consideration which supports the promise of a subscriber to an enterprise is expenditure by the promisee on the faith of the subscription and not advantage to be gained by the promisor" (41 Ill. App. 259; 57 Iowa 307; 69 id. 134). But "until liability has been incurred or acts have been done on the strength of the subscription, it may be withdrawn, and it is revoked by the insanity or death of the inscriber" (96 Ill. 177; 93 id. 475; 77 Pa. 328). The payment by a subscriber of a part of his subscription, which is not legally enforceable, does not make the residue of said subscription valid.

SUBSEQUENT STREAMS. As consequent streams (q.v.) deepen and widen their valleys, new slopes are formed, no longer toward the ocean, but toward the consequent streams. On these new slopes new streams are developed as tributaries to the older rivers. Their courses are not determined by the original but by the subsequent slope of the land, in part influenced by the softer rocks along the sides of the original valleys. These are called subsequent streams.

SUBSIDIES. From the Latin *subsidiū*, support, assistance, composed of *sub*, under, and *sedeo*, I sit. The term subsidies is applied more generally to English law, and the systems in use in this country are brought under the title *bounties*. Subsidies were grants by Parliament of assistance to the king, as taxes or tribute assessed for urgent occasions and levied on all subjects according to their holdings in lands or goods. Later the term applied to aid given by the government to commercial enterprise likely to prove of public benefit. In international law the term applies to money given by one nation to another as an aid to carrying on war without taking active part in such campaign. See **BOUNTIES**.

SUBSTANCE. Ever since Thales explained the universe in terms of water, there has been an almost irresistible tendency among philosophers to explain the unity of intricate assemblages of phenomena in terms of a permanent quasi-material substratum, or, as it is technically known, a substance. The notion of substance runs through the entire pre-Socratic philosophy, and the Platonic realistic hypostasis of the ideas makes of them something very like the substance of the particulars which they embrace. Substance first receives its name and its separation from form in the philosophy of Aristotle, but this separation is by no means complete. Substance, or *τὸ ἰννοειμένον*, is for Aristotle at once something like the explanatory principles of Thales and the other pre-Socratics, and a form or essence endowed with actual existence. Into the form or essence of a particular not all its attributes enter, but Aristotle never makes clear the principle in accordance with which the essential may be separated from the inessential.

The scholastic view of substance is a perpetuation of that of Aristotle. The essence-aspect of substance was transmitted by the Scholastics to the earlier modern philosophers of the Continent; though the latter progressively emphasized the function of substance as a substratum. Descartes makes mind and matter his two substances, and defines substance as that which depends for its existence on God alone. God is clearly the ultimate Cartesian substance. This view is modified by Spinoza, though more in terminology than in fact; he holds that God is the one substance, and that mind and matter are two among His infinite number of attributes. Whether God is simply the sum of his attributes is left uncertain. The Leibnizian concept of substance is not widely different from that of Descartes, but the number of different substances—the monads—is multiplied indefinitely.

The British philosophers from the start mixed less of the Aristotelian notion of form and essence with their substratum-substance than their colleagues on the Continent. Locke followed Descartes in his dualism, but saw that a substratum which is nothing more than a substratum can only manifest itself through its appearances, and is unknowable in its inner essence. Once this became clear, it was obvious that we might remove the substance from the assemblage of appearances overlying it without making any noticeable difference. But of two indistinguishable situations it is impossible to assert categorically that one exists and the other

does not. Berkeley accordingly discarded substance from the realm of matter; he believed, however, that a substantial subject was necessary for cognition. Hume followed Berkeley in reducing the material world to its phenomena, but saw that the notion of substance furnished as little support for the states of a mind as for the qualities of a material object. Combining this with his unwillingness to admit the existence of anything of the nature of a general idea or universal, he was necessarily driven to the opinion that things are mere aggregates of their appearances, which are associated together in a manner quite independent of any inherent relatedness on their part.

The Humian refutation of substance is essentially valid. The very least which we can demand of a principle of explanation is that it should explain; and the explanation of a group of facts is essentially the more intimate correlation of them with the rest of our knowledge. After we have been told that the attributes, say, of the material world are unified through their inherence in a material substance, we know just as little of their bearing on one another and on our remaining stock of information as before. Nevertheless, Hume went too far in denying to the mental and material aggregates of phenomena, respectively, all unity other than that which is furnished by the power of ideas to attract associates. Such collections of entities as the material world, the world of mind, individual minds, etc., have, *prima facie*, a very real unity—the unity, namely, that consists in their forming systems. (It may be shown by such means as are used in the article on *UNIVERSALS* that this unity is not purely illusory). In the post-Humian philosophies, some such notion of system tends to replace the older concept of substance.

In the philosophy of Kant the system-notion of the unity of phenomena and the substratum-notion are both found, and are almost inextricably interwoven. Kant retains the old, unknowable substances of Hume under the name of the Things-in-Themselves. While he regards the existence of these as indubitable, he nevertheless excludes them from any active part in his critical philosophy, in so far as this concerns itself with the pure reason. Within the realm of phenomena, the substances are just such relational, structural complexes as have been described in the last paragraph. Indeed, substance is made a category of relation. The followers of Kant retained this latter phase of his views on substance, and discarded his things—in themselves. They made the entire universe their ultimate reality but though they generally viewed this in the light of a system, there was not wanting among them the tendency to revert to the substratum idea. However, substance, except as the Absolute may be substantial, was not assigned a fundamental status. Thus in the philosophy of Hegel, substance is but a stage of the cosmic dialectic, not its termination.

Though the problem of substance, under its own name, has ceased to play any great part in current philosophical disputes, there are not wanting in the system of the present day entities which differ from substances in little but their appellation. Certainly the Bergsonian *élan vital* serves as a principle of explanation

simply by virtue of being a substratum. There is not a little resemblance between the sense-data and other particulars of modern atomic realism, which serve primarily as pegs on which to hang relations and qualities, and the substances which subserve a like function in the philosophy of Locke. See *MATTER*; *SOUL*.

NORBERT WIENER,

Editorial Staff of The Americana.

SUBSTITUTIONS, Groups of. See **GROUPS, THEORY OF.**

SUBWAYS. Underground railways, now common in cities, have come to bear this name. Of all the difficult problems that have arisen as a result of the great and continuous concentration of population in cities, the most difficult and the most expensive to be satisfactorily solved is the furnishing of suitable and economical means of local travel. With the enormous vehicular traffic that congests the streets, the surface cannot be used except for lines whose speed, being limited by the ordinary street conditions, is too slow, except for short distance journeys. In some American cities, and in a few exceptional cases in European, elevated railroads have been constructed to furnish means of travel on which traffic, freed from surface conditions, could move more rapidly. Such railroads, although successful in themselves, are so unsightly and so objectionable to the abutting houses that they are disliked.

With the surface impossible for use for rapid transit purposes, and with the super-surface undesirable for such use, recourse is necessarily had to the sub-surface, and it is in the development of sub-surface lines that there is the greatest activity. To this class of railroads, and regardless of the method of construction, whether by tunnel or by open excavation, the generic term of Subway has come to be applied. This name is now used to describe a railroad built beneath the surface, with stations at comparatively short distances apart, and primarily intended to serve the needs of local transit in a thickly populated locality.

History.—The first city in the world to feel the need of subways was London, where, in 1853, there was begun the construction of a two-track underground road from Edgeware to Kings Cross. From this beginning there were finally produced two lines, known as the Metropolitan Railway and the Metropolitan District Railway, the greater part of whose construction was finished prior to 1870. These roads were not given a satisfactory location, a compromise route having been determined on by which it was attempted to serve as many districts as possible, the result being that the line lacked directness. This error in proper route selection, and the fact that the railways were necessarily operated by steam locomotives—the only means then at hand—rendering them exceedingly disagreeable for passengers, failed to produce satisfactory financial results, and, consequently, to furnish any encouragement for an early repetition of a similar experiment in London, or, even less so, in other cities, where the demand for transit facilities was less strong. It was not until 1886 that any further attempt was made to construct a subway line; in that year the late J. H. Greathead, an eminent English engineer, designed a railroad circular in section, lined with cast iron, which it was at

first intended to operate with a cable, such method of operation having proved successful in America for surface lines, avoiding the disagreeable consequences of operation by steam locomotives. Before the line was completed it had been demonstrated that such railroads could be successfully operated by electricity, and so that power, instead of cable, was installed.

This tubular railroad, the first to be practically operated, the prototype of many others, having conclusively shown that by means of electricity subways could be operated not only free from the objections of steam operated lines, and free from the objections to the construction of elevated lines, but also more economically than by steam, a serious study of the problem was at once taken up in New York, Boston, Paris, Berlin and Budapest. The last-named city has the honor of having produced a new type of subway, which has influenced the most approved form of construction. This road was built with a flat roof, consisting of steel beams with arches turned between them, permitting the whole structure to be brought close to the surface of the street, and was, therefore, in direct opposition to the Greathead method, in which the railroad was carried at a great depth below the surface of the street, necessitating mechanical means of taking the passengers from platform to street level. This line in Budapest was put in successful operation in 1893. In the meanwhile similar lines had been projected both in New York and in Boston, but owing to certain legal delays in the former city work was first begun in Boston. The latter subway was intended for the accommodation of the surface trolley cars in order to carry them through the congested centre of Boston, where, on account of the narrowness of the streets, the speed of the cars had been necessarily reduced to a rate that was intolerable.

The first subway planned in Boston was partly a two-track structure and partly a four-track structure, and had a length of 1.7 miles. This has since been increased and the subway has also been connected with the elevated railroad system, so that at present both the elevated trains and trolley cars pass through it.

When these various railways were put under construction or in operation, the era of subway construction may be said to have become firmly established, and other lines were undertaken in Glasgow and Berlin, some of the shallow type and some of the tubular type, and elaborate and complex studies were being prepared for both Paris and New York. Although the work of beginning subway construction in these two last-named cities had been retarded for one cause or another, the delay has nevertheless worked to their advantage, as the experience gained at other points had proved of great benefit. These two systems now present the most advanced and the highest development in the art of subway construction.

Work on the first line was begun in Paris in 1898. The French engineers, instead of doing as had been done elsewhere—laying out short and detached lines to serve the most urgent requirements and without regard as to the definite part that such lines would play in the final plan of urban development—laid out, at the beginning, a comprehensive map of a great system covering the whole of Paris, embracing

all the lines that could reasonably be foreseen as necessary or desirable. This plan covers 47 miles of railway, all of which are considered as a unified system to be operated as a whole, and the construction of which has been steadily proceeding.

The work of building the subway in New York did not begin until the year 1900. In no city in the world are the demands for transit facilities as great as in New York. On account of the peculiar shape of the city the main travel is necessarily concentrated on a few well-established north and south lines, and although great as is the carrying capacity of the elevated and surface systems, such capacity is much inferior to the demands of the population. At the time the first subways were opened the number of paying passengers on the street railroads of New York exceeded 1,000,000,000 per annum. It was decided to build a subway railroad with four instead of two tracks. Of these four tracks, two are used for express trains—that is, trains that stop at intervals of about one and one-half miles—and two of the tracks used for local trains, which stop at intervals of about one-quarter of a mile, in order to differentiate between the passenger who desires to travel a long distance and the one who desires to go a short one.

The initial subway had a length of 20.8 miles, of which 6.3 miles are of four-track, 6.7 miles of three-track and 7.8 miles of two-track. This road begins at a point in front of the City Hall, extends northerly to Kingsbridge in the north-western part of the city, and to the Zoological Gardens in Bronx Park in the northeastern part of the city, being in plan like the letter Y.

When this work was about half completed, a second subway was designed and contracted for to extend the above railroad southerly along Broadway from the City Hall and under the East River to a point in the Borough of Brooklyn. This extension consists of 2.8 miles of two-track and 0.7 mile of three-track, making in all 24.3 miles in length, with 86.6 miles of track, exclusive of side tracks. Soon after this first subway was in full operation from Atlantic and Flatbush Avenue Station in Brooklyn to Van Cortlandt Park on the west side and to Bronx Park on the east it was seen that additional transportation facilities would be required within a very few years. Negotiations to this end were initiated by the New York Public Service Commission with the Brooklyn Rapid Transit and the Interborough Rapid Transit in 1911 and on 19 March 1913 the so-called dual contracts were signed by these companies on the one hand and the City of New York on the other. Under these contracts the cost of construction was to be borne partly by the city and partly by the operating companies. The latter agreed also to extend their elevated roads and to increase the facilities of existing roads, by third tracking or by constructing a second story structure. The contracts called for the construction of 44.55 miles of new subways; 53.10 miles of new elevated railways, and 19.8 miles of third-tracking or other additional track. The new lines, now practically completed, consist of 330 miles of single track, made up of 260 miles of subway, 45 miles of elevated and 25 miles of new third track, taken in connection with the

old lines with their 330 miles of track, constitute a mileage exceeding that of all the other rapid transit systems of the world. The year 1918 saw a number of the new lines included in the Dual System placed in operation, leaving to be finished those lines providing new routes between Brooklyn and Queens and Manhattan by tunnels underneath the East River. These tunnels are difficult engineering feats and require a longer time than does ordinary subway or elevated railroad construction. Subsequent to the completion of the first subway the city determined to build certain additional lines, including the so-called tri-borough route in Manhattan and the Bronx; the Centre Street Loop in Manhattan and the Fourth Avenue Subway in Brooklyn. All these lines later were included in the Dual System. Of the Dual System subway lines, there were opened previous to 1918, exclusive of the first or old subway, the Queensboro Subway; the Fourth Avenue Subway in Brooklyn; its 86th street extension; its Sea Beach branch to Coney Island; its New Utrecht avenue branch; the Astoria branch of the Queensboro Subway; the White Plains Road extension of the first subway; the Corona branch of the Queensboro Subway; the Jerome avenue branch of the Lexington Avenue Subway; a portion of the Seventh Avenue Subway; the West Farms Subway connection, and the Broadway Subway, Manhattan. About 170 track miles of new lines were in operation at the beginning of 1918. On 1 July 1918 the new Seventh Avenue Subway was placed in partial operation from 33d street to South Ferry, and on 17 July the new Lexington Avenue Subway was placed in use from 42d street to 167th street in the Bronx. On 1 Aug. 1918 the so-called H system was tried. The beginning of this system terminated the service of the old subway as it had been given for 14 years. Under the H system the old subway from Times square north with its branches was joined to the new Seventh Avenue Subway, thus constituting the west side subway, while the part of the old system south from 42d street and Fourth avenue was joined to the new Lexington avenue line and its Bronx branches, making a complete through line all on the east side from South Ferry to 167th street in the Bronx. This division of the old subway left the part under 42d street from Grand Central Station to Times square as cross-bar to the "H." Its tracks were assigned as follows: Two tracks for a shuttle service between the east side and west side lines, and two tracks for a continuation of the Queensboro Subway west from Grand Central to Times square. Very serious delays in the work of construction of the new lines occurred in 1917-18, owing to the fact that the demands caused by war conditions had been such as to delay the work, and in some respects to bring it to a halt. More subaqueous tunnel work is under construction for Dual System lines than has ever been attempted before. This work represents an expenditure of about \$30,000,000, and includes four new tunnels of two tubes each and one tunnel of four tubes. The last named connects the Lexington avenue line in Manhattan with its Bronx branch. The other tunnels mentioned are the 60th street tunnel connecting the 59th Street Subway with the Queens line, the tunnel

for the 14th street eastern line, the new Interborough tunnel between Manhattan and Brooklyn and the tunnel connection between the Broadway Subway in Manhattan and the Fourth Avenue Subway in Brooklyn.

The total cost of New York's Dual Subway System, including equipment, real estate, powerhouse construction and changes, interest during construction, etc., will be about \$400,000,000. Of this sum about \$60,000,000 is contributed by the Brooklyn Company, about \$146,000,000 by the Interborough, and the remainder, approximately \$194,000,000, by the City of New York.

The general type of subway adopted for New York was of the flat roof shallow form, bringing the rail and platform level as close to the surface of the street as possible. The irregular topography of the city, however, has compelled a departure from this type in several instances, so that a portion of the road is in ordinary deep tunnel, and the portion beneath the East River, and the approaches thereto, is of the tubular type, as adopted in London.

While this work of subway construction had been going on in other cities, London had made many additions to its subway construction by building detached and separately operated lines on the tubular principle, there having been a decided popular prejudice against any form of construction that would threaten to interfere with surface travel during construction, or that would invade the vested rights of the several local governments, which form the constituent parts of the government of the Metropolitan district, or what is commonly known as London.

Construction.—The construction of subways presents a wide field for the display of engineering skill and ingenuity, as a modern line demands the application of nearly all the principles on which engineering science is based. At the time when the first railroad was built in London, iron was expensive, and steel, as a material of construction, unknown, and recourse was had to masonry, except in cases where the use of iron girders was obligatory. The structure was, therefore, a continuous archway, and calls for no extended description.

When the City and South London Railway was begun, cast iron was sufficiently cheap to be used. At that time the building of a line so near the surface as to disturb it, even temporarily, was out of the question, owing to the opposition of various interests. Mr. Greathead therefore decided to make a deep tunnel, which he built by means of a "shield," such as is commonly employed in deep turned work in soft soil.

The advantage attending tubular construction is that it can be carried on without the interruption of surface traffic, but the disadvantages are that elevators must be installed to carry passengers between the platform and street surface, a distance varying usually from 50 to 100 feet, with the attending cost and delay, and the greater difficulty of properly ventilating the deep tubes. On the other hand, a subway built close to the surface of the street, whether by tunneling or in open excavation, introduces many complex difficulties, as there are involved the interference with street travel, and the care and at times extensive reconstruction of other

sub-surface structures, such as sewers, pipes or electric conduits.

In Boston these difficulties were avoided in some instances by tunneling with the aid of a semi-circular shield, and elsewhere reduced, as a rule, by keeping the roof of the subway sufficiently low to pass beneath the water and gas mains, so that they were left in their previous positions. When tunneling methods were not employed, surface travel was maintained by permitting the contractors to break the continuity of the surface during the night only. The first step was to make an excavation across the street and with a length of about 12 feet. This excavation, roofed over with wood during the day, was carried down to the foundation level and a section of the subway structure built. Such an excavation was called a "slice." After the first slice was well advanced, a second was begun, and an intervening slice interval left undisturbed. When a series of alternate slices were completed the intervening excavation was removed.

In Paris, subway construction was much aided by the width of the streets and the placing of nearly all sub-surface structures beneath the sidewalks. In New York, in order to reduce to the minimum the distance between the platform and street surface so as to give the shortest flight of steps for passengers to climb, it was planned to build the old subway regardless of sewers and pipes, even though extensive readjustment was necessary. A general design of a flat roof was adopted, the top of which was permitted to come within 30 inches of the top of the paving, a distance just sufficient to contain the yokes carrying the sub-conduit of the electric surface tramway. In order to support the flat roof with its superincumbent load, a steel framework was devised, consisting of horizontal steel beams in the roof resting on rows of columns between the tracks and vertical steel beams at the sides. These steel frames were set at intervals of five feet, and provide a series of supporting ribs. Between the roof beams and again between the wall beams, arches of concrete were formed. The floor of the structure is also of concrete, reinforced with steel beams, whenever an upward hydrostatic pressure was present. At the sides and immediately next to the wall columns were placed two vertical rows of terra-cotta ducts, into which were drawn, through manholes leading to the street surface, the lead-covered cables to carry the power current for operation. In order to keep moisture from the subway a layer of water-proofing material consisting of felt and asphalt was laid in the floor concrete and then carried up outside of the ducts and over the roof, making a continuous envelope. Immediately outside of the waterproofing was laid a thin protective wall of brick in concrete in order to guard it against damage. For the special difficulties incident to the tunnel construction of the New York subways see **TUNNELS AND TUNNELING — New York Rapid Transit Tunnels.**

The bringing of the subway close to the surface necessitated carrying surface traffic during construction, usually by means of temporary bridges, and the permanent readjustment of sub-surface structures. In the matter of sewerage, this readjusting was done by substituting for a single sewer in the centre of the street, two

smaller sewers, one on each side, and by carrying cross sewers in iron pipes beneath the subway at suitable points. In the matter of water and gas mains, pneumatic tubes and electric conduits, a complete rearrangement was adopted by leaving the smaller ones above the roof and placing the larger ones at the sides. A satisfactory arrangement of these sub-surface structures was a work of great difficulty and expense.

In general the design of this old subway proved very satisfactory, yet in operation certain defects developed which were avoided by the engineers of the Dual System. Many of the stations of the old subway were built on curves. A considerable space was left between the car and station platform on these curves which proved a source of constant danger in rush hours and were the cause of not a few fatalities. Moreover, it is necessary to slow down sooner when approaching a curved platform than a straight one, and in the rush hours, when trains are operated on short headways this slow-down tends to cause congestion at those points of the line where there are curved platforms. The ventilation of the old subway was defective in that all four tracks were placed in one tunnel. The passage of a train there stirred the air, but did not renew it, since the air escaped to the side of the train and was not propelled ahead of it to the exhausts. The new subways have a partition between each pair of tracks, so that there is really a tunnel for trains going in the same direction and one for those going in the opposite direction. Excessive heat developed in the old subway in the summer. This is due to friction of wheels, brakes, etc., and to the operation of the car motors. The old subway was waterproofed all the way around—underneath, at the sides and overhead—and this waterproofing, while most effectively keeping water out, prevents radiation and confines the heat within the tunnel, which is augmented by each passing train. Less waterproofing characterizes all recent subway construction.

On the old New York subway there are two classes of stations, one for local, the other for express trains. The platforms of the local stations are on the outside of the outer pair of tracks, and are reached directly from the street surface, and at these points there is no connection with the express (the central) tracks. At the express stations, the local (outer) tracks are curved outward so as to permit the construction of an island platform between each local and express track. The station stairways in this case are located as before, on the sidewalks and lead to a ticket office beneath the street, from which there leads a bridge passing over the tracks and connected with both the island platforms by stairs. The more important stations cover two streets and have numerous exits and entrances. Straight platforms exclusively are built on the new lines. The openings at subway stations were assumed to be sufficient to provide for ventilation of the subways; but this proved an error, and numerous openings were added, as well as blowers at congested points. See **NEW YORK CITY.**

The cost of constructing subways is very great. In this respect, the New York subway, being the largest and most complete as yet

constructed, has cost (including all work in hand estimated complete) about \$400,000,000. This figure includes many miles of surface and elevated tracks allied with the system, and the usual proportion of "water" for financing the proposition. The most expensive four-track section cost at the rate of nearly \$5,000,000 per mile. In Boston 1.7 miles of subway, a part of which was four-track, cost \$4,250,000. In Paris the cost averages for two-track subway about \$850,000 per mile, while in London tubular railways cost about \$1,500,000 per mile, without equipment in all cases.

Operation.—As stated above, the first subways built in London were worked by steam locomotives. All lines subsequently constructed, except one in Glasgow, have been and are operated by electricity. In the exception above noted a cable was the source of power. As the original lines are now being converted to electrical operation, it has become the sole power now in use. The power is generated in central stations by direct driven generators, usually of large size. The largest central station so far constructed is the station built to operate the subway in New York. In this station there are eight units, which have nominally 5,000 kilowatt capacity each, and which, together with subsidiary engines, represent a total of 132,000 horse power.

The current as produced is, according to the most approved practice, of the three-phase alternating type, and at a pressure of from 6,000 to 11,000 volts. This current, in appropriate substations, is transformed and converted into direct current at a pressure of about 550 volts, and as such is fed to the line. The means of delivering the current to the trains is usually by means of a third rail set on the floor of the subway, and at a distance of about two feet from one of the track rails. From this rail the current is taken by contact shoes on the motor cars and led to the motors themselves. On some railroads the trains are drawn by electric locomotives at the head of the train, coupled in the same manner as steam locomotives. The most desirable practice, however, is to distribute the power to various cars in the train, so that the weight of the cars and passengers furnishes the necessary track cohesion. This method of working is called the multiple unit system. The various motors thus distributed through the train are controlled from either end of the train or can be arranged so as to be controlled at any intermediate point. In the New York subway the most powerfully equipped cars as yet constructed are in operation. The motor cars have each two 200 horse-power motors, and are adapted so that the express trains can be composed of five to seven motors and three trailers. The total weight of an eight-car train, including passengers, standing space occupied as well as seats, is about 300 tons. The nominal power capacity is, therefore, six and two-thirds horse power per ton of train, or, say 10 horse power per ton of train available during the short period of acceleration. This power capacity is greatly in excess of European or other American practice on account of higher speed to be realized. Inasmuch as subways are built to convey large numbers of passengers, it becomes necessary that the cars be run in trains and not in single units, except in the case of Boston, where the

subway was built for the passage of the surface trolley cars. The trains vary in length from 2 to 10 cars.

Ownership.—The various subways in London, as well as in Glasgow, Berlin and Budapest, are the property of private corporations. In England the authorization for such companies has to be procured by a special bill passed through Parliament, the ownership of the work being vested in perpetuity in the corporation, the various powers of the corporation being expressed in the act.

New York, Boston and Paris adopted the principle of municipal ownership, but under different methods of application. In New York the Dual System was created when the city through the Public Service Commission, on 19 March 1913, entered into an agreement with the Interborough Rapid Transit Company and the New York Municipal Railway Corporation (the latter a subsidiary of the Brooklyn Rapid Transit), providing for the construction and operation of new subway lines, elevated and subway extensions, of existing subways, and third tracking and extensions of elevated lines. The city and the two companies contributed large sums for the construction of subway lines, while cost of equipment, plus the cost of construction of elevated extensions and elevated third tracking and other improvements, was met by the two companies on their respective systems. Despite the substantial contributions by the companies to the expense of subway construction, all subways and elevated extensions of subways are owned by the city, while elevated railroad extensions and third tracking on elevated railroads remain the property of the companies. The dual agreements included leases to the companies of the lines to be operated by them and their subsidiaries.

In Boston a commission appointed on behalf of the city constructs the road by contracts as cheaply as possible and makes a lease to the company owning and operating the surface and elevated lines at a figure that will at least return to the city the interest that the city has to pay. In the case of both New York and Boston the profit that the municipality reaps is the securing of the construction of rapid transit lines necessary for the development of the city.

In 1918 the Boston operating company found itself in financial difficulties due to a variety of causes and appealed for aid to the State legislature. An act was passed by the latter body vesting a board of five trustees with power to operate the Boston system and to fix the fare rate. For the first six months of control by the board from 1 July 1918 the success of the experiment was questionable. The fare has since been increased 100 per cent and agitation for public operation has decreased proportionately. Boston's subway now extends to all parts of Greater Boston and to Cambridge, Mass.

In Paris the city arranged with a corporation especially organized for the purpose, the leasing of all lines that the city of Paris might build, the company to pay to the city one-third of the gross receipts, and, in addition, to furnish the equipment, which will become the property of the city at the end of the lease without payment. The city of Paris then constructs in its own name the several lines, which must con-

form to a certain standard of excellence. The company has no supervision of the construction of the lines, as it is not directly interested in the cost. The city of Paris is not secured against loss, as in the case of New York and Boston, but, on the other hand, being practically a partner in the enterprise, it can secure a direct monetary profit, provided the roads are profitable in their operation, which have so far been found to be the case. Chicago and Philadelphia are building subways, construction is well advanced in the latter city. Chicago proposes to spend \$100,000,000 in a nine-year building plan, involving the construction of a double-track rapid transit subway six miles in length and a five-mile subway for street surface cars. These subways would be the nucleus of a larger system to be constructed later, which provides for 58.1 miles of subway. Consult Beavan, A. H., 'Tube, Train, Tram and Car' (New York 1903); McPherson, L. G., 'Transportation in Europe' (New York 1910); Johnson, E. R., 'Elements of Transportation' (ib. 1909). See also TUNNELS AND TUNNELING.

SUCCESSION. Succession is the transmission of property either real or personal at the death of the owner, by rules laid down by law, in distinction to that by will made by the deceased. The term "succession" is used in law to cover both the technical word "descent," which applies to real property, and "distribution," which applies to personal property.

When the owner of property dies, it is presumed that his property will follow in its succession the rules laid down by law, unless it is shown that a will is in existence. This fixes great responsibility upon the law to be just and fair to the survivors, and the statutes of the different States are very carefully worded to cover the rights of all. In all of the States the statutes of descent and distribution show conclusively how property will be disposed of by administrators of estates. The statutes vary in some points, but in most provisions they follow the old common law of England and the Roman civil law.

Family ties form the base on which are built up the laws of succession. Children of the deceased (known as the "intestate" from the fact of not having made a will or testament regarding his property) have the first right in the property. In the United States, except where modified by statute, the heirs or persons who inherit through the laws of succession, take both the real and personal property, the only distinction being that the real property vests at once and the personal is distributed by administrators.

Children, male and female, share alike in the property of the ancestor, and if one or more of the children is deceased, the grandchildren will take that share that would have fallen to their parent, so long as one child of the ancestor lives. If there are no children living, and only grandchildren, all the grandchildren will share and share alike regardless of the apportionment that would have taken place if their parents had lived. The former is known as "per stirpes" or by representation; the latter as "per capita" or by the number of persons.

Property will first descend in a direct line as long as there are descendants, such as to

children, grandchildren and their descendants. These are known as lineal descendants.

It will then go to brothers and sisters of the full blood and to the half blood of the same father, and their descendants. Failing these descendants, it will ascend to the parents and their descendants who are not in the direct line with the intestate, and are known as collateral descendants. Property will descend to even remote kindred before it will ascend one generation.

Where there are no children the husband or wife inherits in some States the entire estate personal and real, but in other States the personal property only is inherited, and the realty descends to the blood of the intestate, a life interest known as dower only vesting in the widow.

The rights of the half blood are settled by statute. Half-blood brothers and sisters inherit from the common ancestor, but not of the parent by marriage.

Where lineal descendants fail, the succession is counted from the common ancestor with the intestate who last owned the property by right of "purchase" rather than by descent. This rule is enforced in order that ancestral property shall not be diverted from its original source.

In the United States there is no preference in descent for male rather than female heirs, nor for first born.

If there are not found any lineal descendants, or any collateral descendants to take the property, the succession fails and the property reverts or "escheats" to the State or county.

Adopted children are treated as not capable of inheriting property other than that of the adopting father and mother, and are not included in succession from other members of the family, either ancestors or brothers or sisters.

A child born after the death of the father is included in the inheritance as if the birth was before the death of the father, if the child is born alive, and the share taken is the same as others of the children.

A bastard may not inherit except from his mother or illegitimate brothers or sisters. Being illegitimate, the law does not recognize rights due him. If legitimized by special act of legislature or subsequent marriage, he takes then in the same share as any legitimate child.

Personal property is distributed according to the laws of the place where the intestate has his domicile. The realty descends according to the laws of the State in which the property is situated. Modern European civil codes differ widely in their provisions regarding inheritance and succession. In general the principles of Roman law obtain. See DESCENT IN LAW; HEIR; INHERITANCE.

SUCCESSION, Apostolic, the transmission, through the episcopate, of the power and authority given by Christ to his apostles for the governance of His church. Theologians of the Catholic Church and of the Anglican High Church maintain that those sects which are without apostolic succession, that is, which separated from the Catholic Church without retaining bishops regularly ordained and consecrated, have, strictly speaking, neither church nor sacraments, nor divine mission to teach their people the truths of the Christian religion. Catholic theologians hold further that apostolic

succession by itself does not involve the authority to teach, to rule the church, to administer the sacraments; that when, for example, a national church goes out of the communion of the Church Catholic, though it have duly consecrated bishops, and duly ordained clergy, by being severed from the Church Catholic it loses jurisdiction, mission, right to exercise the powers of priesthood and episcopacy; its bishops and priests are in a situation resembling that of a bishop or a presbyter who is suspended or excommunicated. See BISHOP; ORDINATION; CATHOLIC CHURCH.

SUCCESSION POWDERS, from the French *Poudres de Succession*, secret poisonous powders formerly prepared in Italy and France, to kill persons slowly, so that their heirs might succeed (hence the name) to their property and personal estate. Private enmities also found these powders a ready and secret means for satisfying the treacherous desire for revenge. Their composition has never been definitely established, but the principal active ingredient is now known to have been arsenious acid, or common white arsenic; then unknown except in the laboratories of a very few chemists. A reference to these powders may be found in Beckmann's 'History of Inventions, etc.,' translated by Johnson (Vol. I, chapter *Secret Poison*). Consult Stenzelii, 'Dissertationes de Venenis et Temporaneis,' resp. J. G. Arnold, Vitebergæ, 1730.

SUCCESSION WARS are wars which arise from claims for the possession of the crown on the occasion of a sovereign dying without undisputed legal heirs. In modern European history the most important of these struggles were those of the Spanish succession (1700-13), and of the Austrian succession (1740-48).

War of the Spanish Succession.—Shortly before the death of Charles II of Spain, without issue or collateral male heirs, several competitors laid claim to the throne, the two principal being the dauphin of France, son of Charles' elder sister; and the Emperor Leopold, who first claimed as male representative of the younger branch of the house of Austria, being descended from Ferdinand, second son of Philip and Joanna of Castile, though he afterward withdrew this claim and substituted another in right of his mother, Mary Ann, daughter of Philip III of Spain. The other leading powers, Great Britain, Germany and Holland, were naturally deeply interested in the settlement of this question, for the union of either France or Austria with Spain, which at that time ruled over the Netherlands, the Milanese, Naples and Sicily and vast territories in America, would have seriously endangered the balance of power in Europe. After much negotiation which had little result, Louis XIV put forward his second grandson, Philip of Anjou, as the representative of the French claim, and Leopold nominated his second son Charles as his substitute, both parties solemnly promising that Spain should never be incorporated with their respective dominions. Charles of Spain's second consort, Mary Ann of Neuburg, being a sister of the empress, naturally promoted the views of Leopold; in which, however, she was opposed by the Count d'Harcourt, a clever dip-

lomast sent by Louis to Madrid, and who conciliated many of the nobles and grandees, whom the queen had alienated. The French ambassador also intimated a resort to force if the rights of the children of France should be superseded. Thus the king of Spain was induced to recognize Philip of Anjou as his heir, 2 Oct. 1700. On 1 November the king died, and the Junta immediately caused Philip to be proclaimed at Madrid. The young king entered his capital 18 February. All the European provinces and all the American possessions of the Spanish empire recognized the new monarch nor was his title at first disputed by the greater part of the European powers. But the measures of Louis excited suspicion and gave offense. On the death of James II of England, the French king recognized his son the Old Pretender as James III; the new works which the French were constructing on the Dutch frontier alarmed the States-General, and on 15 May 1702 England and Holland allied themselves with Austria and declared war against Louis XIV and the "usurper" of Spain. The contest had, however, been already opened by Austria unaided. Prince Eugene descended into the plains of Verona at the head of 25,000 men about the end of May 1701, defeated the French under Catinat at Carpi (9 July), and under Villeroi, at Chiari (September), but this severe fighting had no adequate result. In the following summer Marlborough led an Anglo-Dutch-German army into Belgium and reduced one by one the French fortresses on the Maas; the German states, which, with the exception of Bavaria and Cologne, had been gained by Leopold, sent out an army under the margrave of Baden, which crossed the Rhine and captured Landau. Early in September the elector of Bavaria raised an army and endeavored to effect a junction with Villars, who was sent by Louis to co-operate with him, but they were both kept in check by the margrave of Baden. In 1703 Marlborough, whose actions were hampered by the delegates of the States-General, confined himself to reducing the strongholds held by the French in the low countries. In Germany the elector of Bavaria drove the Austro-German armies out of his dominions, and formed a junction with Villars. The latter advised a rapid march upon Vienna, which might have then been easily captured, but the elector preferred to attack the Tyrol, where the French general Vendôme, with half the army of Italy, was to meet him. The Tyrolese, however, rose against the Bavarians and compelled the elector to retreat before Vendôme could join him. The elector again united his forces with those of Villars, and inflicted a severe defeat on the Imperialists at Hochstedt (20 September); but many misunderstandings arose between the two commanders, and Villars in disgust obtained his recall. In the following year Eugene and Marlborough joined their forces at Donauwörth on the Danube, and coming up with the Franco-Bavarian army under Tallard, Marsin, and the elector, at Blenheim, inflicted upon it a severe defeat, 13 August. In consequence of this decisive victory the French had to recross the Rhine and evacuate all Germany. On the 4th of the same month Gibraltar had been taken in a few hours by a party of English sailors. The

campaigns of Marlborough in the Netherlands and of Eugene in Italy in 1705 have no feature of interest. In Spain the English under the Earl of Peterborough captured Barcelona, and had the archduke proclaimed king as Charles III. The year 1706 was disastrous to the French arms. In Italy the united forces of Eugene and the Duke of Savoy fell upon the French while they were besieging Turin, and gained a complete victory, all the siege artillery falling into their hands (7 September). All Lombardy submitted to the Imperialists, and Charles III was proclaimed at Milan. In the Netherlands, Marlborough routed the French under Villeroi at Ramillies (23 May), and was prevented from besieging Dunkirk only by the jealousy of the Dutch. In 1707 an Anglo-Portuguese army under the Earl of Galway entered Spain, but was met by a much superior Franco-Spanish force under the Duke of Berwick at Almanza, and completely defeated (25 April). In southern Italy the whole kingdom of Naples submitted to a small Imperial army under Daun. Nothing of importance took place in the Netherlands or Germany. Eugene and the Duke of Savoy, penetrating into France by the Maritime Alps and Nice, appeared before Toulon toward the end of July, but the approach of some strong French divisions compelled them to retreat with considerable loss. In the following year Marlborough and Eugene, according to a fixed arrangement, reunited their forces in the Low Countries, and coming up with the French under the Duke of Burgundy and Vendôme at Oudenarde inflicted on them a severe defeat (11 July). The allies then entered French Flanders, and laid siege to Lille, its capital, which capitulated 22 October. On the Rhine both sides remained on the defensive. In Spain Charles III was compelled to shut himself up in Barcelona. The island of Sardinia submitted to Admiral Lake in August, and in the following month Minorca was captured by Lake and General Stanhope. The length and ill success of the war had now begun to tell with fatal effect upon France. The funds required for the equipment and support of the armies were raised by ruinous loans, injudicious and vexatious taxes, the forestalment of future revenue and the issue of paper money and a debased coinage. A severe winter destroyed the corn, vines and fruit-trees, and the dearth and famine which ensued produced discontent and sedition. Louis XIV sued for peace, offering to give up, in the name of his grandson, the whole of the Spanish succession, and to restore Strassburg to the empire; but the allies looked upon these overtures as mere tricks to gain time, and rejected them. Both sides now made extraordinary preparations for renewing the struggle. Villars was sent into Flanders with an army of nearly 100,000 men to oppose Marlborough and Eugene, whose combined strength was slightly superior. After capturing Tournai, the allies proceeded to invest Mons. For this purpose they had to attack Villars in a strongly fortified position at Malplaquet, from which they succeeded in driving him, but not without suffering enormous loss (11 Sept. 1709). After some more fighting, besieging and negotiating, the death of the emperor, Joseph I, son and successor of Leopold, without male issue, leaving his crown to

his brother Charles, changed the whole aspect of affairs. The British thought that if Charles became undisputed sovereign of Spain and her dependencies, the very evil of an almost universal monarchy would be again established, the prevention of which had been the chief cause for taking up arms against Philip V. A new Tory ministry unfavorable to Marlborough having come into power, private preliminaries of peace were signed between France and England 8 Oct. 1711. Eugene, however, continued the war aided by the Dutch, and was pushing steadily forward on Paris, but the defeat and capture of the British contingent under the Earl of Albemarle at Denain by Villars (24 July 1712) so weakened his forces that he was compelled to retreat. This defeat greatly modified the views of the Dutch, and the English government persuaded the States-General to moderate their demands and come to terms with France. On 11 April 1713, the Dutch plenipotentiaries signed a treaty of peace (Peace of Utrecht) with France, their example being immediately followed by Prussia, Savoy and Portugal. Forsaken by all his allies, the Emperor Charles was reluctantly compelled to sign a treaty at Baden, 7 Sept. 1714, in which he recognized Philip V as king of Spain.

War of the Austrian Succession.—On the extinction of the male line of the house of Hapsburg, by the death of Charles VI (20 Oct. 1740), his eldest daughter, Maria Theresa, in terms of the Pragmatic Sanction, (q.v.) claimed the whole of his dominions, and at once assumed the government, with the title of Queen of Hungary and Bohemia. The announcement of her accession was answered by England, Russia, Prussia and the States-General with assurances of friendship and good-will. France returned an evasive answer; Charles Albert, elector of Bavaria, refused to acknowledge the queen of Hungary until his pretensions to the Austrian succession were examined and decided. He appealed to two ancient documents—the marriage contract between Albert V, Duke of Bavaria, and Anne, daughter of the Emperor Ferdinand I, and the testament of that monarch; and he contended that by these two deeds the succession was assured to Anne and her descendants in default of male heirs, the issue of the archdukes, her brothers. Maria Theresa, however, having called together the foreign ministers at her court, caused the testament to be read before them, when it turned out that it spoke not of the extinction of the male issue of Ferdinand's sons, but of their legitimate issue. The first blow against the young queen came not, however, from any claimants of her inheritance, but from a sovereign who had already acknowledged her right. This was Frederick II of Prussia, who, in the middle of December 1740, invaded Silesia at the head of 30,000 men, to sustain an old family claim on four duchies in that province. On the condition that Maria Theresa would cede to him all Silesia, he promised a close alliance with himself, in conjunction with the maritime powers and Russia, his assistance in upholding the Pragmatic Sanction, his vote for her husband as emperor, and an advance of 2,000,000 thalers, but the high-spirited queen, determined not to begin her reign by dismembering her dominions, gave these offers a flat refusal. Owing to an

exhausted treasury and a disorganized army, all Silesia, with the exception of Glogau, Brieg, and a few other places, was overrun by the end of January 1741. A severe winter hindered further operations for a time, but on 9 March the Prussians took Glogau, and pushed toward Jägerndorf. The advance of three bodies of Austrian troops from different quarters now threatened to hem in the Prussians; and to maintain his communications with Lower Silesia, Frederick had to risk a battle at Mollwitz, in which his forces were victorious (10 April). This victory called into action those powers that had postponed their schemes till they had learned the issue of Frederick's attempt. France put herself at the head of a confederacy of all the claimants to the Austrian dominions, the principal among whom were the electors of Bavaria and Saxony, sons-in-law of the Emperor Joseph I; Philip V of Spain; Charles-Emmanuel of Sardinia, who claimed the Milanese, and Frederick II of Prussia, who demanded all Silesia. To this formidable coalition Austria could oppose only a few allies. England granted her an annual subsidy equal to \$1,500,000; the Dutch were arming in her favor; the mixed population of Hungary and the peasants of the Tyrol rose almost in a mass. Toward the end of June the Bavarians entered the Austrian territory, overran Bohemia, and being joined by the French under Belleisle, occupied Lintz, the capital of Upper Austria, without striking a blow. Alarmed by this invasion Maria Theresa bought the neutrality of her most formidable foe, Prussia, by the cession of Silesia and the county of Glatz. On 24 Jan. 1742, the elector of Bavaria was unanimously chosen emperor, with the title of Charles VII, but at the moment when he had attained the object of his ambition his fortune began to turn. Khevenhüller at the head of one Austrian army, advanced up the valley of the Danube, captured a Franco-Bavarian corps 12,000 strong in Lintz (24 January), invaded Bavaria, and on 13 February took possession of Munich, only a day or two after Charles VII's election to the imperial throne had been celebrated there. Another Austrian army under the grandduke of Tuscany kept the French in check in Bohemia. The successes of Austria alarmed Frederick II for the security of his new acquisitions, and he suddenly broke the treaty, poured his forces upon Moravia and Upper Austria, and defeated the Austrians under Prince Charles of Lorraine at Czaslau (17 May). But Frederick was not inclined to push his victory further, he once more made peace with Austria (11 June), and his example was followed by the elector of Saxony. In consequence of these arrangements the French under Belleisle, left without the co-operation of the Saxons, were forced by the maneuvers of Charles of Lorraine to shut themselves up in Prague, where Maillebois, with the French army, was defeated in endeavoring to relieve them. Only 12,000 of the 60,000 men whom Belleisle led into the campaign succeeded in escaping from Prague and making their way into France early in 1743. In the May of that year Bavaria was again occupied by the Austrians under Prince Charles and Khevenhüller. An Anglo-German army of 40,000, under the Earl of Stair, crossed the Maas and Rhine in

March and April, in order to cut off the Bavarian army from France, and coming up with the French under Marshal Noailles at Dettingen completely routed them (27 June), but did not know how to profit by their victory, and nothing was done during the remainder of the campaign. The year 1744 brings with it a new phase of the war; France and Great Britain, which up till this time had been engaged in the struggle merely as allies, declared war against each other. In February a descent was attempted on England, but Admiral Norris, aided by a tremendous storm, proved too strong for the French fleet and the English proceeded to destroy gradually the shipping of the French, and that of their allies, the Spaniards. As a compensation Marshal Saxe conducted a splendid defensive campaign in the Netherlands. Meanwhile the successes of Austria on the Rhine, and the ill-concealed regrets of Maria Theresa for the loss of Silesia, again alarmed Frederick for his possession of that province. He accordingly entered into an alliance known as the Union of Frankfort (22 May), with the emperor, the elector palatine, and the king of Sweden, as landgrave of Hesse-Cassel; a secret treaty was also signed with France, 5 June. A Prussian army of 80,000 men was at once poured into Bohemia, which for a time carried all before it, capturing the capital Prague after a siege of six days, 16 September. The junction of a superior Austro-Saxon force however, and the hostile attitude assumed by the Bohemian population compelled Frederick to quit the kingdom with considerable loss. To avenge this attempt upon Bohemia the Austro-Hungarians broke into Upper Silesia and Glatz, from which the Prussians were almost totally expelled before the end of the year; but before the spring of 1745 the territory was again occupied by the Prussians. Frederick's unsuccessful invasion of Bohemia had proved of service to the emperor, as it compelled the Austrians to return from Alsace, and thus allowed time to recover his electorate of Bavaria. The Italian campaign of 1744 was unfavorable to the Austrians. In the preceding year they had driven the Spaniards almost to the Neapolitan frontiers, and seemed to threaten an invasion of Naples itself. To avert such a catastrophe Don Carlos joined the Spaniards with his forces, and enabled them to drive the Austrians and Sardinians out of the papal territories toward the Po. On 20 Jan. 1745, the Emperor Charles VII died, an unexpected event, which changed the face of affairs. He was succeeded in the Bavarian electorate by his son, Maximilian Joseph, then only 17 years of age. Being too young to make any pretensions to the imperial crown, and the war going so unsuccessfully for his cause, his subjects loudly demanded a termination of their miseries, and he accordingly concluded a peace with Austria, 22 April. The king of Prussia having now no other ally but France, remained on the defensive for a considerable part of this year. He intrenched himself near Jauernik, on the Bohemian frontier, and awaited the approach of the Austro-Saxons. Prince Charles, who commanded them, advanced by Landshut into the plains of Hohenfriedberg, where he was unexpectedly attacked and defeated by Frederick, near Striegau (4 June). Charles retreated into

Bohemia followed by the Prussians, and another battle was fought at Storr, which again went against the Austrians (20 September). About this time the queen of Hungary conceived the bold plan of detaching 10,000 men from the army of the Rhine, who, supported by the Saxons, were to march upon Berlin; while Prince Charles was to attack the Prussian king in his winter quarters in Silesia with another army. Hearing of this project, Frederick determined to anticipate it by an advance into Saxony. About the end of November he entered Lusatia, reduced that province, and marched upon Dresden. The king of Poland (the elector of Saxony) fled to Prague, while Frederick's veteran lieutenant Leopold of Dessau entering Saxony by way of Halle, took Leipzig and Meissen, defeated the Saxon army at Kesseldorf (15 December) and joined the king before Dresden, which capitulated 18 December. Maria Theresa was now compelled to listen to the appeals of the elector of Saxony, as well as to the British Cabinet, which threatened to withdraw its subsidy unless she made peace with Prussia. Frederick was willing to come to terms, feeling that he could not depend on the assistance of France, and that he was unequal to another campaign, his money being almost exhausted. The Peace of Dresden (25 December) assured him of Silesia and Glatz, the cession of which was guaranteed by England, and of an indemnity of \$1,000,000 from Saxony. As elector of Brandenburg Frederick adhered to the election of Maria Theresa's husband as emperor, with the title of Francis I. Meanwhile the French under Marshal Saxe carried all before them in Flanders. The battle of Fontenoy, gained over the Duke of Cumberland and Field-Marshal Königseck (11 May), was followed by the capture of Tournai, Ghent, Bruges, Oudenarde, Nieuport and Ath. Little was done on the side of the Rhine. The Italian campaign of this year was unfavorable to the Austrians. The Spanish-Neapolitan army, now joined by the Genoese and Modenese, and numbering in all 70,000 men, overran the whole of Lombardy and the greater part of Sardinia, compelling the king to seek refuge under the walls of his capital; but in the following year (1746) the battle of Piacenza, gained by the Austro-Sardinians over the Franco-Spanish forces (16 June), compelled the latter to relinquish all their conquests and recross the Alps. On 9 July died Philip V of Spain, and was succeeded by Ferdinand VI, one of whose first steps was to recall his forces from Italy, and the French, unable to hold out against their enemies, retreated across the Var, which left Genoa at the mercy of the Austrians, 6 September. Marshal Saxe continued his career of conquest in Flanders, and in 1747 he entered and overran Dutch Flanders, defeated the Duke of Cumberland at Laffeld (2 July), while his chief engineer, Count Löwendahl, captured, after a siege of two months, the important fortress of Bergen-op-Zoom, deemed by the Dutch impregnable. Meanwhile it was evident that the war was drawing to a close. Though great preparations were being made for another campaign, negotiations had been going on during the winter, and a congress had been appointed to meet at Aix-la-Chapelle, whose first conference took place 24 April 1748. Great

Britain and Holland were weary of the war; France and Spain were almost exhausted, and preliminaries of peace were signed between these powers (30 April); Austria, thus deserted by her allies, grudgingly consented to sign, 18 May; and the definite Treaty of Aix-la-Chapelle was signed by the French, English and Dutch Ministers on 18 October, and in a few days after by those of Spain, Austria, Genoa and Modena.

The War of the Bavarian Succession, between Austria and Prussia, which lasted but little over one year, ended in the Peace of Teschen, 13 May 1779, the elector palatine Charles Theodore retaining possession of the Bavarian dominions. See AIX-LA-CHAPELLE, TREATIES OF PEACE CONCLUDED AT; AUSTRIA; BAVARIA; FREDERICK II; MARIA THERESA; POLISH SUCCESSION WAR.

SUCCINIC (sūk-sin'ik) **ACID**, amber acid, $C_4H_4(COOH)_2$, was first obtained by Agricola (1657) by distillation of amber. It occurs in lignite and fossil wood, in many varieties of plants, in the urine of many animals, and in small quantities in the products of the fermentation of sugar with yeast. In this case it is not a product of the sugar but of the antolytic fermentation of the protein substance of the yeast cells, first into glutamic acid, and the subsequent conversion of the latter into succinic acid. It is usually prepared by the oxidation of fats with nitric acid or by fermentation of calcium malate. A colorless crystalline substance with no odor and a slightly acrid taste; soluble in water or alcohol; melts at $360^\circ F$; heated to boiling point, $502^\circ F$, it slowly loses water, forming the anhydride $C_4H_2(CO)_2O$. It is a dibasic acid forming salts and many other derivatives. The sodium salt has been used in cases of catarrhal jaundice and gallstones. The other derivatives are of interest only to the synthetical chemist. The principal economic use of succinic acid is in its combination with the rare earths of the yttrium group through whose fractional crystallization these rare elements are secured separately.

SUCCINITE. See AMBER.

SUCHET, sū-shā, Louis Gabriel, DUKE OF ALBUFERA DA VALENCIA, French military officer: b. Lyons, 1779; d. 1826. He entered the military service at an early age and passed rapidly through the inferior ranks. In 1796 he was attached to the army of Italy and attracted the notice of General Bonaparte, by his courage, boldness and caution, being made

brigadier-general for distinguished bravery at the battle of Neumark in 1797. He then served with distinction under Massena and Joubert and was one of the most active and successful of Napoleon's generals in the campaigns of 1805 and 1806. In 1808 he received the command of a division in Spain and was almost constantly victorious till after the battle of Vittoria. His brilliant services in that country obtained him the marshal's staff and the title of duke. After the overthrow of Napoleon in 1815 Suchet was shorn of his honors but the rank of peer of France was restored to him in 1819. He left unfinished his 'Memoirs of the War with Spain.' These were published in 1829.

SUCKER STATE, The, a popular nickname for the State of Illinois, whose inhabitants are sometimes dubbed "suckers" by their fellow citizens of neighboring States. The following is the reputed origin of the epithet:

"The western prairies are full of the holes made by the crayfish, which burrows to reach the water beneath the soil. In the early days of the country's settlement travelers armed themselves with slender hollow reeds, which they thrust, when thirsty, into these natural reservoirs, and thus easily supplied their longings by sucking the water through the reed or pipe."

SUCKERS, soft-rayed teleostomous fishes of the genus *Catostomus* and related genera belonging to the family *Catostomidae* (q.v.). The family is extremely characteristic of the fresh waters of North America, where all but two of the 60 or more species are found, replacing in our fauna the carps of the Old World. The 14 recognized genera include, besides the suckers proper, the blackhorse and redhorse, the buffalo-fish, the jumping mullet and the white mullet. Many of these fishes exhibit migratory habits recalling the anadromous marine fishes, moving regularly in the spring from ponds and lakes into the fresher waters of brooks to spawn. As examples of this large group the following may be selected: The common or white sucker (*Catostomus teres* or *C. commersonii*) reaches a length of 15 to 18 inches, has thick protuberant lips with two or three rows of papillae, about 65 scales along the lateral line and a rather short dorsal fin. The color is dusky above, light olivaceous on the side, tinged in the spring with rosy hues. This species is exceedingly common in rivers, mill-dams, ponds, etc., throughout the entire eastern half of the United States. Early in the spring, as soon as the ice is out of the streams, this species leaves the larger bodies of water and deep holes and seeks the swift-running brooks, up which large schools migrate until stopped by some obstruction, to deposit their spawn in the upper stony shallows. At this season they take the hook eagerly, especially when baited with earthworms; but they are listless, lazy fishes and never afford any real sport nor good eating, except for a short time in early spring. In the summer they are soft and tasteless. Many are captured in small nets at sluiceways, etc., or even in the hands by boys who wade in the streams and feel for them under overhanging banks. Hog-sucker, stone-roller (*C. nigricans*) are some of the names of a considerably larger species, with larger scales, found plentifully in the lakes and clear swift streams of much the same region. Its habits are similar and favorite methods of capture are spearing and

noosing with fine copper wire or horse-hair. Other related species are the carp-sucker or sail-fish (*Ictiobus velifer*) of the Mississippi Valley, the carp-sucker of the Susquehanna River (*I. cyprinus*), the chub-sucker (*Erimyzon sucetta*) and the striped sucker (*Minytrema melanops*) of the Great Lakes and Mississippi Valley. Consult Goode, 'American Fishes' (New York 1888).

SUCKING-FISH. See REMORA.

SUCKLING, SIR John, English poet: b. Twickenham, Middlesex, 1609; d. Paris, May or June 1642. He was educated at Trinity College, Cambridge, was admitted at Gray's Inn, traveled in France and Italy and essayed to cut much of a figure at court. Apparently he accompanied the Marquis of Hamilton with the contingent of 6,000 for the reinforcement of Gustavus Adolphus and took part in Tilly's defeat before Leipzig (7 Sept. 1631). In 1637 he had his play of 'Aglaure' presented with large expenditures for its mounting, scenery having, with the exception of masques, been rarely, if at all, used before that on the English stage. He marched at the head of a levy of a hundred horse, recruited by himself, to the Scottish border in May 1639, and he was much laughed at for the gorgeous equipment of his troop. He set on foot the "first army plot," to obtain command of the army for Charles I, but was betrayed to the opposition and compelled to escape to France. The collection 'Fragmenta Aurea' (1646) contains all of his work that is of any importance, comprising 'Poems'; 'Letters to Divers Eminent Personages'; three plays, 'Aglaure,' 'The Goblins' and 'The Tragedy of Brennoralt,' and a tract on socinianism, 'An Account of Religion by Reason.' His plays are valuable largely for the interspersed poems. Suckling is called by Aubrey the inventor of the game of cribbage. There is a volume of selections by W. C. Hazlitt (now ed., 1893). Consult 'Works of Sir John Suckling,' edited by A. Hamilton Thompson (New York 1910).

SUCRE, Antonio Jose de, ãn-tõ'ně-õ hõ-sã' dā soo'krā, Venezuelan military officer: b. 1793; d. June 1830. He entered the insurrectionary army in 1811, and in 1819 he had attained the rank of brigadier-general. With the assistance of the Peruvians under Santa Cruz he gained the decisive victory of Pichincha, 24 May 1822, which was immediately followed by the capitulation of Quito. He totally routed the Spanish forces in the battle of Ayacucho, 9 Dec. 1824, the most brilliant ever fought in South America. Sucre promptly followed up this glorious victory and his troops entered Cuzco on 12 December in triumph. Upper Peru was soon entirely liberated and turned into a republic called Bolivia, of which Sucre was elected President in 1826. An insurrection broke out in 1828 and Sucre was driven from the country; but he returned at the head of a Colombian army and reinstated himself. He was assassinated in the neighborhood of Pasto.

SUCRE, or **CHUQUISACA**, choo-kě-sā'-kā, Bolivia, the capital of the republic and of the department of Chuquisaca, in the extreme northwestern corner of which it is situated, 318 miles southeast of La Paz. It is now reached by rail from Mollendo, Peru, via La Paz and

from Tacná and also from Argentina. It lies on a plateau to the west of the eastern Cordillera, 8,987 feet above the sea, and is surrounded by beautiful mountain scenery. The houses are well built and surrounded by gardens. A fine cathedral and a number of other public buildings testify to the former wealth of the city. Sucre is also the seat of the oldest university in Bolivia, as well as of other high educational institutions. The Supreme Court of Bolivia sits at Sucre. Sucre was founded in 1536 on the site of the Indian village of Chuquisaca. In the Colonial period it was called La Plata and soon acquired great wealth and importance from its rich silver mines. It was later eclipsed by Potosi, but is still the centre of a prosperous mining and agricultural region. Although it is officially the capital, the national government is now chiefly administered from La Paz. Here Bolivian independence was proclaimed on 6 Aug. 1825. The city was later named after Sucre, first President of the new republic. Pop. 24,000.

SUDAN, soo-dān', or **SOUDAN**, is the Arab name given to the vast extent of country in central Africa which lies between the Sahara on the north, Abyssinia and the Red Sea on the east, the countries draining the Kongo Basin on the south and Senegambia on the west. Its area is estimated at 2,000,000 square miles, and its population at from 10,000,000 to 20,000,000. The inhabitants comprise numerous nations of different races, chiefly the negro, together with Arab colonists and traders. The western and central Sudan are divided into a number of states which until recently maintained their semi-independence. It is now virtually all controlled by England and France. Bambarra, Gando, Sokoto, Adamawa, Bornu, Baghirmi, Wadai and others. The eastern Sudan includes Darfur, Kordofan, Senaar, etc. Egyptian rule was first extended to the eastern Sudan in the early part of the 19th century by Mohammed Ali, under whom Ibrahim Pasha carried it as far south as Kordofan and Senaar. An Egyptian expedition under Sir Samuel Baker in 1870 led to the conquest of the equatorial regions on the Nile farther south than the Sudan proper, of which General Gordon was appointed governor-general in 1874. On the fall of Ismail Pasha of Egypt, Gordon was recalled and hordes of Turks, Circassians and Bashi-Bazouks were let loose to plunder the Sudanese. Egyptian misrule then became intolerable, and in this crisis appeared Mohammed Ahmed of Dongola, who gave himself out to be the Mahdi, the long-expected redeemer of Islam. (See EGYPT), Emin Pasha (Eduard Schnitzer) was appointed governor of the equatorial province on the Upper Nile, north of the Albert Nyanza, by Gordon in 1878.

During 1881-82 the Mahdi destroyed nearly every Egyptian force sent against him, but in the spring of 1883 elaborate preparations were made to suppress the rebellion. A well-equipped army, organized and commanded by Colonel Hicks, an old Anglo-Indian officer who had entered the Egyptian service, began its march up the Nile in September with the intention of striking at once at El Obeid, the headquarters of the Mahdi. But, after enduring many hardships, Hicks' army was led by a treacherous guide into an ambushade and anni-

hilated. Colonel Coetlogon, the British officer at Khartum, at once adopted defensive measures, and called in as far as possible the outlying garrisons. After some further reverses the British government advised the khedive to relinquish the country south of Wady Halfa or the second Nile cataract. English troops were sent out to relieve the garrisons of Eastern Sudan, and General Gordon undertook to effect the withdrawal of the garrisons of Khartum and other places, unaccompanied by English troops. In a short time he was shut up in Khartum, and in the autumn of 1884 a British force under Lord Wolseley was sent up the Nile to effect his relief. This expedition was too late to accomplish its object. Khartum was stormed by the Mahdists in January 1885, and Gordon was butchered.

After the successful revolt of the Mahdi the Red Sea and Somali possessions of Egypt were occupied by Italy and Britain, respectively, and Darfur threw off the Egyptian yoke, but the equatorial province was held by Emin Pasha till he was relieved by Stanley. In 1896 an Egyptian force under the sirdar, Sir Herbert Kitchener, proceeded up the Nile, occupying Dongola on 23 September of that year, and taking possession of Abu Hamed and Berber during 1897. Early in September 1898 the Mahdist forces, under the command of the Mahdi's successor, the Khalifa, were completely defeated at the battle of Omdurman and Khartum was reoccupied by the Egyptian forces. About the same time the question of the southern limit of the Egyptian Sudan was raised by the occupation of Fashoda, a little north of the Sobat River, by a French force under Major Marchand. By an Anglo-French agreement in 1899 the western boundary was drawn so as to leave Wadai to France and Darfur and the Bahr-el-Ghazal to the Egyptian Sudan. In the same year the 22d parallel of latitude was declared to be the northern boundary of the Egyptian Sudan, which is now under the government of Britain.

SUDBURY, Canada, town and capital of the district of the same name, Ontario, situated to the north of Georgian Bay, on the Canadian Pacific, the Canadian Northern and the Algoma Eastern railroads, 443 miles west of Montreal and 182 miles east of Sault Ste. Marie. The branch to Sault Ste. Marie leaves the main line here. Two short railway lines connect the town with its celebrated mines of nickel and copper. The ores are partly reduced in furnaces near the town. The town is the seat of a government school of mines and of a Jesuit college. Pop. 4,150.

SUDERMANN, Hermann, German dramatist and novelist: b. Matziken (near Heydekrug, East Prussia, 30 Sept. 1857). His father was a brewer, descended from a family of Dutch Mennonites, one of whom was the didactic and moralistic author Daniel Sudermann (1550-1632), who wrote in German. Hermann Sudermann attended the Realschule at Elbing, the Realgymnasium at Tilsit, earning a living at the same time as an apothecary's apprentice, and went to the University of Königsberg, where he studied philology and history until 1877. In the latter year he went to Berlin and became a tutor to various Berlin families, including that of the author Hans Hopfen (1835-1904). He then turned to journalism (his first charge was that of co-editor of the *Deutsches Reichsblatt*, 1881-82), which was to be his introduction to literature. In 1891 he married the authoress Klare Lauckner, a widow (née Schulz, b. 14 Feb. 1861). Sudermann later retired to a villa at Grunewald, a suburb of Berlin, and now spends much of his time at his castle of Blankensee, near Trebbin, which the enormous royalties on his plays enabled him to acquire. But his first successes were not in the field of the drama, but in the novel and short story. 'Im Zwielficht' ('In the Twilight'), a volume of short stories, appeared in 1887 (36th ed., 1910), followed in the same year by 'Frau Sorge' (English translation may be had under the name 'Dame Care'), his most famous novel. The latter is a powerful, simply constructed, objective work, excellent in suggestion of tone and milieu, with a somewhat sensational ending. Björnson's story, 'Arne,' was probably used as a model, and Sudermann's work in turn served as the model for Frensen's great success, 'Jörn Uhl.' The 125th edition of 'Frau Sorge' was printed in 1912. After another volume of short stories ('Die Geschwister' 1888), came another strong but somewhat more vulgar novel, 'Der Katzensteg' (1889; English translation to be had under the title 'Regina'). Although his talent as a narrator is very great, he felt his skill as a dramatist to be greater, and in the same year (1889, which is the year of the opening of the realistic movement in the German theatre (consult arti-

cles on Fontane, Gerhart Hauptmann), his first play, 'Ehre' ('Honor') was played in the Lessing Theatre, Berlin, on 27 November. This play, which had been originally intended to be a tragedy, and which, on Blumenthal's advice, had been conducted to a 'happy ending,' was a pseudo-Nietzschean attack on the morality of the lowly and had a great success. The next play, 'Sodoms Ende' (5 Nov. 1890), a tragedy of artistic life in Berlin, was not a success. It was followed by 'Heimat' (7 Jan. 1893), in which Sudermann again emphasizes the right of the artist to a freer moral life than that of the petty bourgeoisie, and which is constructed with such telling dramatic effect, that this play has carried Sudermann's reputation all over the world. Every great actress considers 'Magda' (in English the play is known by that name), the heroine of 'Heimat,' to be one of the touchstones of her profession. There is in this play some of the moralistic and didactic tendency of the later French dramatists, especially the younger Dumas, and all of their technical finesse. Sudermann attempted another long novel, 'Das hohe Lied' (English translation, 'The Song of Songs') in 1908. His latest work of which any report has reached this country is the dramatic cycle 'Die entgötterte Welt' ('The World made Godless'), of which one section, 'Die gutgeschnittene Ecke' (performed at the Lessing Theatre, 28 Jan. 1916), treats satirically of the sordid commercial phases of theatrical art in Berlin. On the whole, Sudermann must be regarded as a seeker for sensational effect and high royalties, in which he has been extremely successful. The permanent value of his work is slight. But its present popularity renders it important to study it as a symptom of the times. His other works are 'Iolanthes Hochzeit' (short story, 1892); 'Es war' (novel, 1894); 'Die Schmetterlingsschlacht' (1895); 'Morituri' (three one-act plays, 1896); 'Das Glück im Winkel' (1896); 'Johannes' (1898); 'Johannisfeuer' (1901); 'Es lebe das Leben' (1902); 'Das Blumenboot' (1905); 'Strandkinder' (1909); 'Der Bettler von Syrakus' (1911); 'Der gute Ruf' (1912). See MAGDA.

JACOB WITTMER HARTMANN,

The College of the City of New York.

SUDETEIC MOUNTAINS, or **SUDE- TENGEIRGE**, soo-dě-těn-gě-brě'gě, Germany, a range of mountains running along the northeastern boundary of Moravia and Bohemia, which it separates from Silesia. It rises from the valley containing the headstreams of the Oder, north of the Carpathian Mountains in Moravia, and ends on the southern boundary of Saxony, where the Elbe separates it from the Erz Mountains. Its length is 192 miles. It is a continuous ridge only in its middle portion, which is known as the Riesengebirge. The two ends spread out in the form of plateaus traversed by numerous minor ranges. The slopes are covered with pine forests below which are fertile fields, while the higher summits are bare. The highest point, Schneekoppe, has an altitude of 5,265 feet. The range, which consists mainly of primitive rocks, is rich in minerals, especially iron, lead, copper and zinc. Coal is found in paying quantities in the southeastern quarter of the range.

SUDRAS. See CASTE.

SUDWORTH, George Bishop, American dendrologist and botanist: b. Kingston, Wis., 31 Aug. 1862. He was graduated at the University of Michigan (department of literature and science) 1885; instructor of botany in State Agricultural College of Michigan 1886; botanist in United States Agricultural Department from 1889 to 1898 and dendrologist in the Bureau of Forestry and forest service of the same department since 1898. He has written numerous papers and works on North American trees and is a member of various scientific societies.

SUE, Marie-Joseph Eugene, *mārē zhō-zěf è-zhān sū*, French novelist: b. Paris, 10 Dec. 1804; d. 3 Aug. 1857. He adopted his father's profession of medicine, became a surgeon in the army and served in Spain in 1823. In 1825 he joined the naval service and in the capacity of surgeon was present at the battle of Navarino in 1827. On his father's death in 1829 he inherited an immense fortune and, having abandoned his profession, he devoted himself to literary composition. His first work was a sea novel entitled 'Kernock le pirate,' which was quickly followed by 'Plick et Plock,' 'Atar-Gull,' 'La Salamandre' and 'La Vigie de Koat-ven.' He now entered the departments both of historical fiction and the novel of real life. Of the former description were 'Latreaumont,' 'Jean Cavalier' and 'Le Commandeur'; of the latter were 'Arthur,' 'L'Hôtel Lambert' and 'Mathilde.' But his most famous works are 'Les Mystères de Paris' and 'Le Juif Errant,' well known in English as 'The Mysteries of Paris' and 'The Wandering Jew.' His later novels are 'L'Enfante Trouvé,' 'Les Sept Péchés Capitaux' and 'Les Mystères du Peuple.' In 1850 he was elected to the Constituent Assembly and sat as an advanced radical. After the *coup d'état* by Napoleon III in 1851 he was exiled and retired to Annecy. See WANDERING JEW, THE, and consult Mirecourt, Eugène de, 'Eugène Sue' (4th ed., Paris 1870).

SUESS, züs, Eduard, Austrian geologist and seismologist: b. London, England, 20 Aug. 1831; d. 25 April 1914. He studied at the Universities of Prague and Vienna and was appointed (1852) assistant of the Court Mineral Cabinet. In 1867 he was made professor of geometry at the University of Vienna, in the same year being elected member of the Akademie der Wissenschaft, Vienna, of which he was vice-president in 1897, and president from 1897-1911. He wrote 'Entstehung der Alpen' (1875); 'Zukunft des Goldes' (1877); 'Zukunft des Silbers' (1892); 'Das Antlitz der Erde' (1883-1901).

SUET. See TALLOW.

SUETONIUS, swē-tō'nī-ūs (full name, GAIUS SUETONIUS TRANQUILLUS), a Roman writer, the son of a military tribune, flourished about 100 A.D. Little is known of the circumstances of his life. He distinguished himself as an advocate, obtained the tribuneship through the influence of Pliny the Younger and was appointed secretary to the Emperor Hadrian. His chief works are 'Vitæ Duodecim Cæsarum' and the treatises 'De Illustribus Grammaticis' and 'De Claris Rhetoribus.' The former work gives an interesting account of the 12 first Roman emperors from Julius Cæsar to Domi-

tian and is of great value from the light which it throws on domestic manners and customs. Among the best editions of Suetonius are those of Wolf (1802), Baumgarten-Crusius (1816-18) and Roth (1858).

SUEVI, swē'vi, the general name of a number of united tribes who, before the Christian era, inhabited the greater part of Germany. The Hermunduri, Semnones, Lombards, Angles, Vandals, Burgundians, Rugii and Heruli were the most important, at least the best known. In Cæsar's time they advanced to the Neckar and the Rhine. The Visigoths overcame them entirely in 586 and their empire and name disappeared from Spanish history.

SUEZ, soo'ez, Egypt, town on the borders of Arabia, situated at the north end of the Red Sea, and at the south end of the Suez Canal, 76 miles east of Cairo, with which and with Alexandria and other towns it is connected by rail. Formerly it was a small, ill-built, miserable-looking place, badly supplied with fresh water; but the construction of the Suez Canal, and of the fresh-water canal from the Nile, has caused a great change. The fresh-water canal has been taken advantage of for irrigation, which has quite altered the appearance of the land around. In the town the houses, offices and warehouses of European merchants are now to be seen in every direction. Among the principal buildings are the Greek church, viceroy's villa, two hospitals, custom-house, etc. There is here a salt manufactory established by the Egyptian government. A stone pier carrying a railway stretches from the town across an extension of the Red Sea (dry at low water) to Port Ibrahim, at the mouth of the Suez Canal. The population before the construction of the canal was 1,500; at present it is in excess of 18,000.

SUEZ, Gulf of, an arm of the Red Sea, lying along the east coast of the Sinaitic Peninsula.

SUEZ, Isthmus of, an isthmus which unites Asia and Africa, and separates the Mediterranean from the Red Sea; now intersected by the Suez Canal.

SUEZ CANAL. This great canal, which may be said to have converted Africa into an island, runs for nearly 100 miles from Port Said on the Mediterranean to Suez on the Red Sea, forming a channel navigable for large vessels between the two. It is not the first work of the kind constructed in the same locality—a large canal from the Red Sea to the Nile being known to have existed from six centuries before the Christian era to the latter part of the 8th century after it, when it finally became choked up and useless. Napoleon I, when in Egypt, had thoughts of making a great ship canal across the isthmus; and from that time various schemes for accomplishing this were proposed. At last, about 1854, M. Ferdinand de Lesseps, a French engineer, obtained from the late Saïd Pasha, viceroy of Egypt, the concession or exclusive privilege of making a ship canal from Suez to Tineh on the Mediterranean; and after his plans had been weighed and debated for years he was able to form a company in 1858 for the purpose of carrying them out. Half the shares were taken in France, one-fourth in Egypt and very few in England,

mainly owing to Lord Palmerston's objections on political grounds and Robert Stephenson's on engineering considerations. After many compromises the following important conditions were agreed to: The land on both sides of the canal is to be retained by the company for 99 years. The quantity of this land is only to be sufficient for the purposes of the canal and for the various works at Port Said, Ismailia, and Suez; none of it is to be sold to other parties. All persons residing upon the conceded land are to be subject to the same local and consular jurisdiction as residents in other parts of Egypt. Some of the privileges originally granted to the company by the viceroy of Egypt were bought back by him at very high prices; some others he was unable to fulfil and paid a corresponding compensation by remitting certain demands which he would have been otherwise entitled to make. In these and in other ways the viceroy became largely interested in the scheme. In November 1875 the British government bought from the viceroy his interest in the canal, consisting of 176,602 shares, for \$20,000,000.

The work was begun on 25 April 1859 and it was estimated that the canal would be wholly completed in 1864, at a cost of \$30,000,000. It was opened only on 17 Nov. 1869, and the total cost was about \$80,000,000. Large numbers of men were of course required for the works, and crowds of Fellahin, Arabs, Nubians, Negroes, Sicilians, Greeks, etc., were engaged upon them, while dredges and other machines of great power were also employed. To facilitate the construction of the great canal a service canal 20 feet wide and five deep was constructed for part of the distance, by which men and materials could easily be conveyed. A canal was also constructed for bringing fresh water from the Nile at Bulak near Cairo, since without an extensive supply of this necessity of life the canal works could not have been carried on in the waterless region of the isthmus. This canal reaches the salt-water canal at Ismailia, about midway between the Mediterranean and the Red Sea, and then runs almost parallel to the course of the ship-canal till it arrives at Suez. Previously existing canal works were partly available for the fresh-water canal. It has proved a boon to the country all along its banks. It is about 40 feet wide and 9 deep, and is used for navigation as well as for domestic purposes and irrigation. From Ismailia to Port Said fresh water from this canal is conveyed through large pipes. Plugs are inserted in the pipe along the route where necessary to allow the withdrawal of water for domestic or other purposes. The great canal itself differs in dimensions in different places, being narrowest where the amount of cutting was greatest. For about four-fifths of its length (77 miles) it was at first 327 feet wide at the surface, 72 at the bottom and 26 deep; for the remainder (22 miles) it was only 196 feet wide at the surface, the other dimensions being the same. Many portions of the canal were easily enough made, but at other points the excavation demanded an immense amount of labor. In one place the workmen had to cut a passage 90 feet deep and 200 wide through sandstone rock. Port Said was chosen as the Mediterranean entrance of the canal instead of Tineh, be-

cause here the deep water is nearer the shore. It has grown up since the works commenced, and possesses basins, quays, a lofty lighthouse with electric light, etc., and a harbor protected by two breakwaters or piers, the one 2,070 yards long, the other 2,730. Leaving Port Said the canal first passes for about 24 miles along the eastern margin of Lake Menzaleh, an extensive and very shallow lagoon. The water of the lake is not admitted into the canal, which is confined between embankments, and is from 26 to 29 feet deep—much deeper than the lake. Beyond Lake Menzaleh occurs a sandy strip of three or four miles, after which the canal enters Lake Ballah, where embanking and dredging had again to be resorted to; passing through this for about eight miles it next runs through a land portion of the same length, in which occurs the formidable cutting mentioned above, and it then reaches Lake Timsah, about half way across the isthmus. This is a small lake, and had long been dry, but is now filled with sea-water, and abounds with fish. Lake Timsah is a stopping place for vessels passing through the canal, and affords a large space suitable for anchoring. Between Port Said and Lake Timsah the canal is nearly straight, and between the former place and Lake Ballah quite so; the southern half of its course is more winding. On the western shore of Lake Timsah is situated the town of Ismailia, which owes its existence entirely to the canal and the railway which connects it with Zagazig, Cairo and Alexandria. At Ismailia the fresh-water canal is connected with the great canal by means of locks, their levels being different. In the nine miles through which the great canal is carried after leaving Lake Timsah enormous quantities of rock had to be removed; then come the Bitter Lakes, like Lake Timsah formerly dried up, but now filled with sea-water; then a length of 17 miles, partly through a shallow lake, partly through a sandy desert, after which the canal reaches its terminus at Suez. Extensive works have been constructed here, among which are a mole 850 yards long; a dry dock, 413 feet by 95, built by the Khedive of Egypt; another, 360 feet by 85, for the Peninsular and Oriental Company, etc.

The shipping passing through the canal has steadily increased since its opening. In 1870, 486 vessels, of a total burden of 654,915 tons, sailed through it, yielding the company an income of \$1,032,000; in 1874, 1,264 vessels of 1,649,188 tons passed through and the receipts amounted to over \$5,000,000. In 1913, 4,979 ships of a total tonnage of 19,785,040 passed through the canal, the passengers on these ships numbering 282,235. In 1918, 2,522 vessels of 9,251,601 net tons passed through the canal. The following table covers the ships of those nations chiefly represented in 1913:

NATIONALITY	Number	Tonnage
British.....	2,902	11,887,170
German.....	771	3,317,593
Dutch.....	338	1,283,986
French.....	255	925,709
Austro-Hungarian.....	244	840,068

The tolls charged were nine francs per ton for laden passenger or cargo steamers and warships; six and one-half francs per ton for ships in ballast without passengers and 10 francs for each passenger. Successive reductions in the tolls in 1911, 1912 and 1913 have made the charges equal to the rates proposed for the Panama Canal. (See PANAMA CANAL). The fact that Britain was miserably represented on the board of management in course of time created much dissatisfaction among British shipowners, and in 1883 there was much talk about the construction of a second canal. This came to nothing, but led to the widening and deepening of the existing canal and the construction of large basins to allow north and south-going vessels to pass each other. The depth is now (since 1913) 36 feet, accommodating vessels of 31½ feet draught. An electric lighting system has also been installed which permits of navigation being carried on at night. The distance between London and Bombay by the old route round the Cape is about 11,220 miles; by the new route opened up by the canal 6,332 miles. Steamships are allowed to sail at a speed of five to six knots an hour along the canal. Consult 'Statesmans' Year Book.' See CANALS.

SUFFERN, N. Y., village of Rockland County, on the Erie Railroad, 32 miles north by west of New York. It has iron works, foundry, etc. Pop. 2,663.

SUFFIELD, Conn., town in Suffield township, Hartford County, on the New York, New Haven and Hartford Railroad. It is 16 miles north of Hartford and has chiefly tobacco and cigars as its manufactures. Pop. 3,841.

SUFFOLK, sūf'ōk, Va., town and county-seat of Nansemond County, on the Nansemond River, and on the Atlantic Coast Line, the Southern, the Seaboard Air Line, the Norfolk and Western, the Norfolk and Southern and the Virginian railroads, about 20 miles southwest of Norfolk. It is in an agricultural region. The chief manufacturing industries are woolen mills, lime kilns, lumber mills, iron works, grist mills, peanut factories, machine shops and truck package plants. Large quantities of oysters are shipped during the season. According to the government census, there are in Suffolk 100 manufacturing establishments, with over \$2,000,000 capital invested and employing over 3,000 persons. The cost of material used annually amounts to more than \$1,060,000. There are three banks with a combined capital of \$210,000. The educational institutions are the public schools. Pop. 7,008.

SUFFOLK (Va.), Operations Around and Siege of. Soon after the occupation of Norfolk and Portsmouth by the Union troops, 10 May 1862, a force was pushed out to occupy Suffolk, 25 miles southwest of Portsmouth by the Seaboard and Roanoke Railroad, and at the head of Nansemond River, by which it had communication with the mouth of James River, and also Petersburg and Richmond by the Norfolk and Petersburg Railroad. It was not only an important outpost to Portsmouth, and the key to the mouth of James River, but also the key to all operations in the region bordering on the Nansemond and the Dismal Swamp, and was a favorable point for operations against the

Weldon and Petersburg Railroad. The Confederates began active measures to reoccupy the place. Late in August it was held by General Mansfield with about 6,000 men and six guns. About half of the garrison was withdrawn early in September and sent to the Army of the Potomac, and with them went Mansfield. Taking advantage of the reduction of the garrison, the Confederates began preparations to attack the place, and on 22 September Gen. J. J. Peck was placed in command, with 9,000 men, under orders to repel the advance from the Blackwater of a reported column of 15,000 Confederates, under Generals French and Pettigrew. On the 25th Peck began the construction of a system of defenses, encircling and covering the place, which, by the end of January 1863, mounted 60 heavy guns. Early in January 1863 the Confederate authorities came to the conclusion that Peck was preparing a base of operations for a grand movement on Petersburg and Richmond, in co-operation with the Army of the Potomac, and began the construction of a series of works from the line of the Blackwater to Fort Powhatan, on James River.

General Peck was a vigilant officer, and made frequent reconnaissances of the Confederate positions along the line of the Blackwater, bringing on several collisions at Franklin, Zuni and other points, during the months of October, November and December 1862. Late in January 1863 General Pryor, who for some time had commanded a Confederate brigade on the Blackwater, crossed to the east side of that stream on a foraging expedition. He had three Virginia regiments of about 1,800 men and seven guns. On 30 January Gen. M. Corcoran, with a regiment of cavalry, five of infantry and 12 guns, in all about 4,800 men, started from Suffolk at 1 A.M., and at 3.30 A.M. the cavalry came upon Pryor's camp at Kelly's store, nine miles west of Suffolk. Artillery was run forward and engaged that of the Confederates for nearly three hours, when the infantry advanced, and after a short contest Pryor fell back two miles to a strong position, from which he was forced and pursued as far as Carrsville. Corcoran returned to Suffolk the same night, with a loss of 23 killed, 108 wounded and 12 missing; Pryor's loss was 8 killed and 31 wounded.

General Lee, informed that Union troops were being sent down the Potomac with the evident intention of operating against Richmond by the south side of James River, on 18 February ordered General Longstreet, with two divisions of his corps, to Petersburg and placed him in command of all Confederate troops south of James River, including those in North Carolina, to defend Petersburg and Richmond. Late in February Longstreet had, not including those in North Carolina, about 24,000 men, 12,000 of whom were on the line of the Blackwater, and 12,000 near the railroad to Petersburg, so posted that within 24 hours he could concentrate them all near Suffolk. It was left entirely to his discretion whether he should assume the offensive, but he saw the importance of confining Peck at Suffolk, and of collecting all the subsistence in that section of the country and getting it inside the Confederate lines, and Longstreet began a very thorough system of foraging. He employed the month of March in constructing elaborate defenses on the Blackwater, in assist-

ing Gen. D. H. Hill in his operations against Newbern, Washington and Plymouth, N. C. (qq.v.), and in gathering all the forage and subsistence possible, under Lee's orders "to draw from the invaded districts every pound of provision and forage." He reported to Lee on the 30th that there was no particular advantage in giving battle at Suffolk, nor was it prudent to make the attempt, unless he could get assistance from the navy in protecting his left on James River and the Nansemond. On 4 April he advised Lee of his intention to cross the Blackwater in a few days to get what supplies there were east of the stream, and, if he found it possible, to make an effort to get the Suffolk garrison. He crossed the Blackwater by pontoon-bridges on the 10th, and on the 11th, in three columns of nearly 20,000 men, advanced on Suffolk, capturing some of the Union outposts on the way, halting only when he came under artillery fire from the advanced works of the Suffolk defenses. Peck was fully prepared; he had been watching for the movement, and 14 March had been reinforced by General Getty's division of the Ninth corps, raising his command to 15,000 men. Admiral Lee, at Fort Monroe, was asked by telegraph to send gunboats up the Nansemond to prevent Longstreet from passing that stream and thus getting to the rear of Suffolk and the railroad to Portsmouth. Lee promptly responded by sending two flotillas of tugs (by courtesy called gunboats) to hold the river, one of eight boats, under Lieutenant Lamson, to hold the upper Nansemond, and one of four, under Lieut. W. B. Cushing, to hold the lower Nansemond. Longstreet's first move was to control and blockade the upper Nansemond, a narrow, tortuous stream, about seven miles long. For this purpose batteries were erected under cover of darkness, and on the morning of 14 April they opened fire on Lamson's boats, disabling one, seriously injuring others, and driving all into the lower Nansemond. In the afternoon of the 19th Lamson opened a heavy fire upon Stribling's Virginia battery, which had been put in an old work at Hill's Point, a tongue of land just above the junction of the Western Branch and Nansemond, and after a heavy cannonade one of his boats, carrying 270 men of the Eighth Connecticut and 89th New York, ran in shore and landed the men, Lamson following with four howitzers. They carried the work, capturing five guns, 55 gunners and 71 officers and men of the 44th Alabama. Next day the guns were carried across the river and the work abandoned. The erection of batteries gave Longstreet control of the upper Nansemond, but he made no effort to cross it, in the face of Getty's division on the eastern bank. He demonstrated on the lines west and southwest of Suffolk, but found no weak point in them, and did not consider an assault advisable, reporting to the Confederate Secretary of War 17 April: "I have not fired again at the enemy's stronghold, nor do I expect to do so. I am very well convinced that we could reduce it in two or three days, but doubt if we can afford to expend the powder and ball. To take it by assault would cost us 3,000 men. . . . The principal object of the expedition was to draw out supplies for our army. I shall confine myself to this unless I find a fair opportunity for

something more." On 29 April he wrote to Gen. D. H. Hill: "I am of the opinion that I can hold my position against any attack from the front. We shall be here two weeks longer hauling out supplies." Hooker had now opened his Chancellorsville campaign, and on the 29th Longstreet, with his army, was ordered to return to Fredericksburg and join General Lee. It took him four days to call in his foraging trains and get them beyond the Blackwater. D. H. Hill was recalled from North Carolina, and on the night of 3 May Longstreet withdrew and recrossed the Blackwater, his rear-guard being closely pursued to that stream next day. The greatest number of troops Longstreet had before Suffolk was about 20,000. Peck had 30 April about 25,000. The loss of the Union army was 41 killed, 223 wounded and 2 missing. There was small loss in the navy. The Confederate loss is unknown. When it was definitely ascertained that Longstreet had withdrawn from the Blackwater, leaving only French's division of about 5,000 men to observe Peck, General Dix ordered Peck to take up all the rails on both railroads from the Blackwater to Suffolk and send them to Fort Monroe, and suggested to the authorities at Washington that Suffolk should be abandoned for a more defensible position on the line of Deep Creek, eight miles from Norfolk. The suggestion was approved, the position at Deep Creek fortified, the roads dismantled, under several attempts of French to prevent it, nearly 7,000 tons of railroad iron removed, the 100 heavy guns in the works around Suffolk withdrawn, the works leveled, and 3 July Suffolk, except as an outpost, evacuated. Consult 'Official Records' (Vol. XVIII, XXVII); 'Naval War Records' (Vol. VIII); The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

SUFFREN DE SAINT-TROPEZ, sū-frān də sǎn trô-pă, Pierre André de, French naval officer: b. Saint-Cannat, 17 July 1726; d. Paris, 8 Dec. 1788. He entered the navy at 14. In 1772 he was commissioned captain. Early in 1777 he sailed to America, and his ship began the indecisive battle of Grenada on 6 July 1779. He next served with the allied fleet blockading Gibraltar, and early in 1781 was placed in command of a squadron of five ships for service in the East Indies. Sailing to Madras, he fought a hard but indecisive battle off Madras, and soon after, in a bloody two-days' battle off Providien on the coast of Ceylon, proved himself a consummate master of naval tactics. Having captured Trincomalee, he two days later stood out of the harbor with 15 ships against the English 12, and fought a hard but indecisive battle. His last fight (June 1783) was also indecisive. Suffren arrived in Paris early in 1784, and was received with the greatest honors, and created Vice-Admiral of France. He was called also the Baillie de

Suffren, an office he held in the Knights of Malta.

SUFISM, soo'fizm or sō'fizm (Arab. *Tasawwuf*, being or becoming a Sufi), is Mohammedan mysticism. It derives its name from the Arabic *sufi*, mystic, "clad in wool" (from *suf*, wool), because most of these mystics clad themselves in woolen garments or carry a woolen headdress. Some philologists connect the word with the Greek *σοφός* "wise," but their theory is untenable. Sufis often call themselves *urafa*, "Gnostics" or "Theosophists," namely, those who possess a special and esoteric knowledge of divinity. Travelers of to-day in Persia, Egypt, India and Turkey commonly call them fakirs or dervishes (Arab *fagir*; Pers. *darvish*), that is, "the poor," "beggars," and the name is correct both in a good and a bad sense with this proviso that not all beggars are fakirs or dervishes.

The origin of Sufism is disputed. Some will derive it from the Vedanta and Buddhism, but their theories have no real foundations and fall to the ground when it is remembered that Vedanta is pantheistic and that Sufism in the main follows the Theistic lines of the Koran. Some even refer to it as an offshoot of Christianity. Sufis themselves reckon it to be older than its known historic forms and it seems quite probable that there was Sufism before the Sufis. As early as the 2d century after the Flight, asceticism and ethics and with them Sufistic quietism and the disinterested love of God, assumed a prominent position in Islam, and as fate would have it, contrary to Mohammed's explicit order, this new feature arose in his own family with the favorite Ali. The name seems first to have been used by Abu Hashim (780 A.D.); but Abul Said Chair is mentioned as founder (about 820 A.D.). Legendary lore, which has surrounded the pious woman Rabia al Adawiyya (725 A. D.) with much Sufistic halo, calls her the first Sufi and tells numerous stories about her quietistic disposition, all of which are profoundly characteristic of early Sufism.

Early Sufis are profuse in their expressions about their "Union with the Beloved" (namely, God), and that has probably led some Western scholars to confound the mystic union with the pantheistic *tat tvam asi*, "That (the Universal Spirit) art Thou." Most Sufis of to-day are very moderate in their claims compared with their early predecessors, and declare that they are simply esoteric Mohammedans and place more value upon the "inner doctrine," which they see behind the external forms, than upon the direct Koranic word. The inner meaning or doctrine which they read in such a verse as the following, which refers to the battle at Bedr, "Thou didst not shoot when thou didst shoot, but Allah shot," minimizes individualism and makes the deity "all there is," but in no wise All.

Essentially, Sufism is an inner and personal experience or feeling of God. In this respect it is as original as any other mysticism, but in its outward forms it has borrowed, like any other mysticism, from its environment. Its immediate cast is Mohammedan, but its speculative and doctrinal forms are in the main drawn from Parseeism, Peripatetic Philosophy and Neo-Platonism. From the first it draws a large

part of its rich symbolism. The two latter were brought to it by the seven Greek philosophers whom Justinian's intolerance drove into exile and who found a welcome refuge at the court of Nushirwan, the Sassanian king. Sufis do not like to admit this, but it is a fact.

Sufism is primarily not a doctrine, but an experience, a "feeling." When it expresses itself intellectually it finds outlet in two principal doctrines, that of the *One* (Ahad) and the *Way to the One* (Tariqat). The first declares that there is not only "no god but God," but that there is nothing but God, a teaching which excludes all pantheism, inasmuch as it never says that the All is God, only that God is the All, and emphasizes that the world is a phantom, an unreality. The second doctrine: "The Way to the One" contains the whole of the Sufis' ethics and is practically the main burden of all Sufi conversation. There are many methods or "Ways" (Tariqat) to "Union with God." They say "The Ways unto God are as the number of souls of men"; but they all begin with ascetic practices and end in a contemplative beholding of the Divine.

Most of them include the well-known Dervish dances, absolute silence for several years, and other occult practices.

Sufism is rich in symbolism and some of it is familiar to readers of Hafiz and other Persian Sufi poets. A symbol is to a Sufi rather more than an emblem or a figure of speech; it is what he calls a "veil," that through and by its material form reveals the Deity. When Hafiz and Omar Khayyam in true Sufi fashion glory in wine, for instance, they do not glorify intoxication in any other sense than that in which it was used about Spinoza, namely, that he was full of God—a "God-intoxicated man." Wine is to them a form or manifestation of God, as it is in the sacrament to the Christian. When they sing its praises, their song is a hymn and spiritually they partake in a mystery. A Sufi is not a drunkard nor a licentious man. The "wine and women" of the reveler has no place in asceticism and the inner life. That Sufi poets should use such strange language has always been a mystery to the uninitiated, who likes to read the Sufi's language literally and believe what he says literally.

Sufis lay more weight upon the conception of God as the "Eternal Beauty" than most religious and mystics. God creates because he is beauty, it being the essential nature of beauty to reveal itself. The act of creation consisted in God throwing His reflection on "the mirror of not-being," and creation itself is thus only a reflection, a contingent being.

Man is the eye of creation, the point through which the Divine looks out and the one who, if he loves wisdom, goodness and beauty, can overlap his individual limitations and attain "Union with God," the goal of Sufism.

In addition to the already mentioned famous Sufis are to be reckoned Dhun-Nun (859 A.D.), who formulated the doctrine of ecstasy and prepared a scale of mystic steps; Junaid (910 A.D.), who wrote about Sufism; Al-Ghazzali (411 A.D.), and Jallal-ud-Din Rumi (1262 A.D.), the two most famous Doctors of Sufism. Omar Khayyam is now known in the West mainly in the negative light of Fitzgerald's paraphrase

and by (thus far) the only Sufi interpretation by the writer of this article. Almost all the famous Persian poets were Sufis, namely, Attar, Anvari, Nizami, Hafiz, Saadi, Jami, etc.

A Sufi Publishing Society, Ltd., has been established in London by Inayat Whan in 1915. He is of the Chistee Order and is the Pir-O-Murshid of the order in the West. Sufism is also being preached in America, but has as yet no recognized headquarters and director.

A large number of the Ottoman poets are also Sufis. Consult following Sufi works: Jalal-ud Din Rumi, 'Mathnawa'; Attar, 'Mantigat-Tair'; Shabistari, 'Gulsan-i-Raz'; Al-Ghazzali, 'Alchemy of Happiness'; 'The Divan of Shamsi Tabriz'; Tholuck, 'Sufismus'; Palmer, E., 'Oriental Mysticism'; Gibb, 'History of Ottoman Poetry'; Browne, E. G., 'Literary History of Persia'; Nicholson, J. A., 'Selected Poems from the 'Divan-i-Shams-i-Tabriz' and Nicholson, Reynold A., 'The Mystics of Islam.'

SUGAR ACT. See ACTS OF TRADE.

SUGAR BEET. See BEET; BEET-SUGAR.

SUGAR-BIRD, one of the small, insectivorous honey-creepers (genus *Certhiola*) of the West Indies (except Cuba). Some species of which are called banana-quits, quit-quits, etc., which come about the grinding mills and warehouses where sugar is kept, attracted by the multitude of insects there. These little birds, on account of their familiarity and their pretty plumage, are favorites and often enter dwelling-houses, where they hop gravely about the furniture and explore the room after spiders and other prey which the housekeeper will willingly part with. In their figure and motions they remind a Northern naturalist of a nut-hatch, while their coloration—black, yellow, olive, gray and white—recalls to him a tit-mouse. They generally keep in pairs and build a rather rude domed nest, which finally holds three red-specked eggs. There are many species, several of which are peculiar to single islands. Consult Gosse, 'Birds of Jamaica', and Cory, 'Birds of the West Indies.'

SUGAR GROWING AND SUGAR MAKING. Sugar (French, *sucre*; German, *zucker*; Spanish, *azucar*) is a substance of the formula $(C_6H_{12}O_6)_n$. There are other substances, lactose, maltose, etc., of this formula and of the formula $C_6H_{12}O_6$, that are termed sugars, but they differ in their characteristic properties from cane sugar or sucrose, which is sweeter and more pleasant to the taste than any other natural saccharine substance, unless it be levulose ($C_6H_{12}O_6$) which is formed by the inversion of sucrose. Levulose is a constituent of honey, the fine flavor of which is due largely to this sugar. It will be seen from the sucrose formula that sugar is composed of carbon, hydrogen and oxygen and the two last in proportion to form water, hence the term carbo-hydrate applied to it and many other similarly constituted bodies, such as starch ($C_6H_{10}O_5$) and dextrose or grape sugar ($C_6H_{12}O_6$). The theory of the formation of sugar as well as that of some other similar bodies, is that carbon dioxide combines with water to form a substance, formaldehyde, of the simple formula CH_2O . This then becomes the nucleus of the sugars and carbo-hydrates

and possesses the property of polymerization (uniting with itself to form a larger molecule of similar percentage composition) by which they are built up. The term sugar, in its strictest sense, means cane sugar and while it occurs in many plants and flowers, its manufacture for commercial purposes is confined almost entirely to the sugarcane and the sugar-beet, though small quantities are made from a certain variety of the maple tree, from sorghum and from the date palm.

CANE SUGAR.

Historical.—Although sugarcane (*Saccharum officinarum*) is now cultivated in all tropical and semi-tropical countries, its origin and that of its manufacture into sugar date back to the remotest antiquity and both remain somewhat in obscurity. However, the majority of evidence traces sugarcane to India as the home of its origin, though George Richardson Porter in his work entitled 'The Nature and Properties of Sugar Cane,' says, 'The strongest proofs, carefully collected from the authorities of ancient and modern times, lead to the conclusion that China was the first country in which sugarcane was cultivated and its produce manufactured.' Another author (Prinsen Geerligs) states, 'No real preparation is recorded before about 600 A.D., at which time a Chinese emperor sent a man to learn the art of sugar-making in India, for in the year 500 A.D., white sugar is mentioned as being shipped from India to Europe.' The views of Dr. H. W. Wiley and Prof. W. C. Stubbs agree with Prinsen Geerligs. In the 8th century sugarcane was extensively cultivated in the Nile delta and in this century the Arabs introduced it into Sicily and from there it was transported to Spain. It appears that the sugarcane was carried into Siam, Ceylon and Japan from China. A sugar trade existed between Syria and France in the 12th century. From France it was transported to Holland, from Holland to Italy and thence to Germany. Sugarcane was introduced into Santo Domingo soon after the discovery of America and from there it spread to Cuba and adjacent islands. It was introduced into Mexico in 1520, Brazil in 1532, Martinique in 1650 and Guadeloupe in 1644. It continued to spread through South America.

The manufacture of sugar up to this time was very crude. Inefficient mills operated by wind, water or oxen, were used for extraction; lime, clay and ashes as purifying agents; the evaporation was effected in open copper or iron pans placed directly over the fire and the refining consisted in melting, boiling and recrystallizing. These crude methods exist yet in some countries, especially in districts where cane is grown for making syrup and very crude sugar. Sugarcane was introduced into Louisiana from Santo Domingo by the Jesuits in 1751. Dubeuil built the first cane-mill and his efforts at manufacturing failed. The first refined sugar was made by Antonio Mendez in 1792, but the first refined sugar on a commercial scale was made in 1794 by Etienne De Boré. The plantations of these two planters now form a part of the city of New Orleans.

Varieties.—The variety of cane grown by them was called "Creole." The principal present varieties, "stripped" and "purple," were intro-

duced in 1820 by Mr. Coiron, the first to use the steam-engine for extraction. He secured them from a planter in Savannah, Ga. These varieties are natives of Java and their introduction into this State gave a great impetus to the new industry. Dr. W. C. Stubbs, while director of the sugar experiment station of Louisiana, introduced two seedling canes known as D-74 and D-95, which have proved very superior to any varieties grown previously; the former is a green cane and better than the latter, which is purple. Since the success of Boré the industry has continued and reached its maximum yield, 710,827,438 pounds, in 1894-95, while other Southern States (chiefly Texas and Florida) the same year produced 18,565,123 pounds, making a total of about 325,621 long tons. Alabama, Mississippi and Georgia grow cane extensively, on a small scale, for the manufacture of syrup which is also produced in Louisiana, Florida and Texas.

Description.—Cane grows from 5 to 15 feet in height and from one to two inches in diameter. It is made up of short sections connected by nodes or knots, the spaces between the nodes being termed inter-nodes or joints. The nodes have on them a bud or eye and are made up largely of non-saccharine content, while the inter-nodes contain most of the sugar. With proper conditions of temperature, moisture and soil the eye swells, bursts and puts forth a young cane which emerges from the soil with one leaf (being endogenous) which is rolled and tapers to a sharp point. In a few days a leaf is observed, which gives place to a bud. As the plant grows leaves are formed on alternate sides of the nodes and below the eyes. The leaves grow to a length of about three feet, two inches wide at the base and taper gracefully to a point. When only a few weeks old, the plant will begin to exhibit nodes and inter-nodes, which are at first green. As the plant matures some continue green, while others become purple, striped, yellowish-green, etc., the color depending on the variety, of which there are a great many. As the cane matures the first leaves (those at the bottom) turn yellow, lose vitality, dry up and fall off, leaving the lower portion of the stalk bare while the upper portion continues green, succulent and growing until killed by frost or arrested by maturity, when it flowers and seeds. It is only in tropical countries that cane flowers and the time required for this is from 12 to 15 months.

Propagation.—Sugarcane is a perennial plant and can be propagated by layers or cuttings, or seed, the former being generally practised, the latter to cross-fertilize and produce new varieties. The entire cane may be planted, but the upper portion is thought best for seed. In many countries this portion is used for seed, but in Louisiana and adjacent States the tops are thrown away except a small portion fed to stock during harvesting. The Louisiana planter claims that labor is too scarce at harvest time to take care of this part of the crop, which would, by taking off the partially-matured joints, be ample for seed. The cane is cut near the surface of the ground, leaving a stubble or "ratoon" which sprouts in the spring and is capable of producing a second and even a third crop in Louisiana, and in tropical countries 5 to 10 crops can be grown with but one planting,

though the general practice, where cane and labor are abundant, is to plant annually or biennially. The tendency of the young canes is to sucker and a large portion of the crop may come from suckering, especially if the stand is poor. The crop from the plant cane is larger than that from stubble in Louisiana, but the reverse is true for two or three years in the tropics and each successive stubble crop is less than the preceding. The stubble cane is richer in sugar and has more fibre than plant cane and is not considered as good for seed as the latter.

Soil, Its Preparation; Cultivation.—Sugarcane is grown more or less in all tropical and semi-tropical climates and the soil in which it can be grown may be of very varying character. A suitable soil should be very fertile, capable of retaining a large amount of moisture and with enough clay in the sub-soil to prevent leaching of the soluble constituents, at the same time it should be well drained. Cane grows well in the Southern States (Georgia, Florida, Alabama, Mississippi, Louisiana and Texas) in both sandy loam and clay loam soil, but the alluvial soils of the valley lands are best adapted for growing cane. The preparation of the soil is a very important feature of cane culture. If the land should be at all stiff or very clayey, preparation should take place or begin in the fall. The lighter soils of a porous or loose character may be prepared just before planting. It is customary in this country in preparing the soil to throw it up in ridges, five to seven feet apart, and when this is done in late summer or in the fall with a large quantity of vegetable matter, whether of grasses or peavines, the soil is in fine condition for planting in early spring. In rotation of crops corn and peas usually follow cane.

Planting.—The planting of the cane consists in opening the ridges and putting the cane into a deep furrow and then covering with a plow, sometimes rolling after covering. One, two or three canes may be planted along side by side in Louisiana or other Southern States growing cane, but in the tropics short pieces may be planted. It is the custom of some to cut the cane in lengths of 18 to 24 inches before planting, while others cut it only where it is crooked, the object being to make it lie well in the furrow. Recent experiments in Hawaii have shown cutting to be of great value in securing a good stand. In some countries only the upper portion of the cane is planted, for reasons already given. The quantity required per acre varies from four to six tons, thus requiring a large investment in seed cane on a large plantation.

Preserving Seed.—The seed-cane is preserved through winter by windrowing or matting, the former being more generally practised. Windrowing consists in cutting and piling the cane in a continuous row between the ridges in such a manner that the tops and leaves cover up the butts of the cane, after which dirt is thrown over, sufficient to cover the cane or partially cover it. Matting differs from windrowing chiefly in having trash or grass thrown over the cane before it is covered. Cane thus preserved is not altogether protected from hard freezes nor from "dry-rot" in case of very dry weather.

Fertilization.—The fertilization of the

cane is very important, as one fertilizer may tend to grow a heavy tonnage with small saccharine content, while another may grow less tonnage but proportionately more sugar. The fertility of the soil is maintained by the addition of commercial fertilizers, distributed either in drill or broadcast, by rotation of crops and by growing heavy crops of pea vines.

Cultivation.—The cultivation should begin as soon as the cane is well up and has for its object the destruction of weeds and grass and maintenance of good tilth. Frequent moving of the soil to a very shallow depth is advantageous, while deep plowing is very injurious. It is necessary to hoe the cane from one to three times. The cane is usually laid by in this country in the latter part of June or the first of July and the implement used for this final work is the disc plow which throws the soil well up around the roots of the cane, leaving it on a high ridge, the chief purpose of which is to aid in drainage.

Drainage.—The drainage of the valley lands in Louisiana is very important and expensive. The land is cut into small pieces varying from two to five acres, with a system of mains and laterals to take off the excess of water.

Irrigation.—Irrigation should be practised, if possible. This is essential in some of the islands of Hawaii. The water is applied by allowing it to run in the furrows. Irrigation is practised very little in Louisiana.

Harvesting.—Cane has about eight months to produce sugar in this country, while in Hawaii, Cuba and other tropical countries its growth may extend over one year or 18 months before being harvested. The harvesting period in this country is from October to January, in those, from January to mid-summer. Cane is usually cut by hand, though cane-cutting machines have been in operation of recent years. These, however, have not been perfectly satisfactory. The instrument used for cutting cane is a large steel knife, with a blade about five inches wide, 18 long and provided with a little hook on the back. The cane is cut at or near the surface of the ground, the leaves stripped off with the hook, the top cut off at the last matured joint and the cane put into piles along the rows. From here it is taken up, either by hand or machinery, put into carts and laid across large ropes, or put into cars, and transported to the factory. Here the cane is taken out by hand or machinery and if the latter, it is accomplished by a derrick which lifts the entire load by means of the rope on which the cane has been laid. These large bundles are piled up around the factory and when the cane is to be crushed, it is taken up by the same machine, elevated to an incline, dropped on it and slides down to the cane carrier and thence to the mill.

Extraction.—There are in practice two methods of extracting the sugar from cane, namely, milling and diffusion. The older and more generally used is milling, the diffusion being confined almost entirely to manufacture of sugar from beets. A mill may consist of two or three rollers, usually placed horizontally, and vary in length from 18 inches to 72 inches, and in diameter from 12 to 32 inches. If the mill is to be operated by oxen or by horses the

rollers are set in an upright position. The most primitive mill was the wooden roller. This has been used in a small way in some of the Southern States since the Civil War, but there is at this writing, perhaps, not one in existence in this country. In most large factories there are two of these three-roller mills and in some, three. The rollers are so arranged that two are placed on a level and geared to move in the same direction while the third moves in the opposite direction. If a factory operates two mills the rollers of the first are further apart than those of the second, and if three mills, the third has its rollers closer together than the second. These rollers revolve very slowly (one and one-half to two and one-half revolutions per minute) and are operated under great hydraulic pressure. To relieve the strain upon the mill, a cane crusher or shredder has come into general use. The cane enters one of these as it leaves the cane carrier and is either crushed or shredded into small pieces before reaching the mill. This not only relieves the mill of the work of crushing the whole cane, but increases its capacity. The capacity of mills will vary from 200 to 1,400 tons of cane per day and the extraction is 70 to 80 per cent on the weight of cane and 90 to 95 per cent of the sugar in the cane. Between the first and second mill the juice receives a spray, through a perforated pipe, of either hot or cold water, the object being to dilute the sugar so a larger percentage will be crushed out by the second mill. This addition of water is termed maceration and the quantity of water added may vary from 5 to 15 per cent of the weight of the cane and in some cases as much as 20 per cent, the quantity depending somewhat upon the value of fuel and the capacity of the evaporating outfit. In some instances the diluted juice from the third mill is returned and used for macerating the crushed cane between the first and second mill, and water is used between the second and third. The value of maceration may be seen from the following estimate taken from practice: It has been estimated that maceration increases the extraction from four to six pounds of sugar per ton of cane. A factory crushing 500 tons daily and operating for 90 days, would crush a total of 45,000 tons. An increase of five pounds per ton would yield to this factory 225,000 pounds of sugar. This quantity at 3.5 cents per pound (the price paid for 96 test last season in Louisiana) would amount to \$7,825. Supposing that 10 per cent of water on weight of cane was used, then for every ton of cane there would have been 200 pounds of water or approximately 25 gallons. It is estimated that one pound of coal will evaporate about eight pounds or one gallon of water. Then the 25 gallons of water would require 25 pounds of coal. Coal being valued at \$4 per ton or 20 cents per 100 pounds, 25 pounds would be worth five cents, this deducted from 17.5 cents, the value of five pounds of sugar, leaves 12.5 cents as the net value gained per ton of cane and the 45,000 tons would be worth \$5,625.

Diffusion.—Extraction by diffusion is treated under beet sugar and it is necessary here to give only a brief statement with reference to diffusion as applied to sugarcane. Diffusion has been practised at several factories in Louisiana

and some other countries, but it has not yet met with very great favor. The diffusion process in Louisiana has been abandoned. There are claimed for diffusion the advantages of a purer juice and a higher percentage of extraction. In a battery used for sugarcane, the juice will vary in sucrose from .3 per cent in the last of a series of 12 to 14 cells, to 16 per cent in one freshly filled. The disadvantages of this process are, large amount of water to evaporate, more skilled workmen required and the chips are not so good fuel even after running through a press, which causes additional expense.

The Utilization of Bagasse.—The cane after receiving its final crushing, whether passed through two or three mills, contains from 40 to 50 per cent of water and is, therefore, a poor fuel if its value be estimated on the weight of bagasse. If allowed to accumulate it would become a great nuisance about the factory, hence it is consumed as fuel. If the ash contains silica and alkalis in proportion to form a fusible mixture, a slag will result and choke the furnace by forming a coating over the gratings; for this reason the burning of a mixture of bagasse and molasses has not been satisfactory. Notwithstanding its high water content, it supplies about two-thirds of the fuel in the Louisiana sugar factory and practically all of it in the tropical countries where the percentage of fibre is from 2 to 3 per cent more than in this State. Six tons of wet bagasse or three of water-free, are said to be equivalent to one ton of ordinary bituminous coal. Experiments at a very great cost have been made to produce paper from bagasse at Sugar Land, Tex., and at Kenilworth Sugar Factory in Louisiana. Neither has been a commercial success, though there has been a considerable amount of rather an inferior grade of brown paper from these mills put on the market in this section. The Kenilworth mill cost about \$300,000 and it is said that the running of it for one year added to this amount \$50,000 to \$60,000 more. This mill is shut down and the bagasse from the last crop was consumed as fuel. The manager of this mill claims that the percentage (about 30 per cent, according to his estimate) of paper-producing fibre is too small, that the color is poor and bleaching is too expensive and that the paper is wanting in strength. The opinion of the writer is that a fair test has not yet been made.

Clarification.—The juice as extracted by the mill has a gray or dark green color, an acid reaction, and contains sucrose, glucose or dextrose, perhaps a little levulose, gums, albumen, organic acid, pectine, the ash or mineral constituents, earthy and coloring matter, fine particles of suspended bagasse, etc. The following analyses show the composition of three samples of Java cane juice taken respectively from first, second and third mills in triple crushing:

These results indicate the composition of cane juice in Java and other tropical countries where cane is grown under most favorable conditions. In Louisiana the juice has from 10 to 15 per cent sucrose, 1 to 2.5 per cent glucose or reducing sugars and the non-sugars vary from 1 to 3 per cent. There is usually a difference of 2 to 3 per cent sucrose and even more in some instances from the beginning, October, to the end, December and January, of the grinding season. The reducing and non-sugars also vary very much between the opening and close of the grinding. The purpose of clarification is to remove the impurities as far as possible. This is accomplished by chemicals and heat, causing the soluble impurities to become insoluble or solid. These are removed by settling or filtration. The principal chemicals are sulphur, lime and phosphoric acid. Sulphur is applied as sulphur dioxide which bleaches, disinfects, coagulates some of the albumen and prepares the juice for taking more lime, thereby causing a heavier precipitation which brings about a mechanical cleansing. Sulphur is not much used in the tropical countries where the juice is of a high degree of purity, but it is extensively used in Louisiana and other sections where the juice contains large portions of impurities. Lime is universally used and is the most important of all the chemicals employed in the sugar factory. It neutralizes acids, acts upon the gums, albuminous substances, coloring matters and, if added in excess, upon the glucose, converting it into organic acids. The lime compounds thus formed are largely insoluble, but some of them are soluble, the insoluble portion is removed by settling or filtration and much of the soluble can be got rid of by the addition of phosphoric acid to form the insoluble tri-calcium phosphate, or in some cases sodium carbonate, to form the almost insoluble calcium carbonate. Phosphoric acid is also used to correct any alkalinity resulting from excessive liming and sodium carbonate is very essential in properly correcting the acidity of sour juices. Lime salts, if left in solution in any considerable quantity, give trouble by depositing on the coils of the "effects" and "pans," thereby reducing their efficiency in the evaporation. Carbon dioxide is used to correct alkalinity and remove excess of lime.

Defecation.—To carry out the process of clarification the juice as it leaves the mill is strained through a copper-wire gauze, then drawn into a sulphur box or tank, if sulphur be used, where it is thoroughly mixed with sulphur dioxide which is produced by the burning of sulphur in an appropriate oven nearby. From the sulphuring apparatus which may consist of a box in which the juice and "sulphur gas" are mixed by a pump or of a cylindrical rotating and inclined vessel in which the mixing takes place by rotation, the juice is drawn into measuring tanks of 2,000 to 6,000 gallons capacity. The clarifiers are rectangular or circular metal-

lic pans, 700 to 1,200 gallons capacity, provided with a steam coil. These pans may be used also for measuring. In some cases the juice is heated before entering the clarifier, in others it is heated in them. Milk of lime, prepared by slaking and grinding, in especially constructed machines, is added in the clarifiers in sufficient quantity to neutralize, or leave slightly acid, or slightly alkaline, according to the practice of the factory, acid juices being worked to produce high-grade sugar and alkaline or neutral to produce low grades. The necessary quantity of lime required for a given quantity of juice is not easily determined. Several methods are in use for this purpose: (1) By the addition of lime until it shows a desired reaction with litmus or turmeric papers. (2) By testing a litre or gallon of the juice with milk of lime and applying the same proportion in the clarifier. (3) An approximate quantity is added, the juice heated, agitated, a small portion filtered and tested with sucate of lime (prepared by shaking powdered lime with a 20 per cent sugar solution) which forms a precipitate if an insufficient quantity has been added. More lime is then added and the sucate test repeated. This testing is repeated until the necessary quantity is obtained (Prinsen Geerligs). (4) The acidity of the juice is determined with a tenth normal caustic soda solution, using *phenolphthalein* as an indicator. An approximate but insufficient amount of lime according to the soda test is added, the juice heated, agitated, a small portion filtered and again tested with the soda. Now the exact quantity indicated by the soda may be put into the clarifier. On heating the limed juice a portion of the impurities rise to the surface, while others fall to the bottom. In some factories the settling takes place in the clarifiers, while in others the boiled juice is drawn off into large cylindrical tanks provided with conically-shaped bottoms, which facilitate settling. If the former method is used it is the practice of some to brush off the scum of impurities into a trough attached to the side of the clarifier and then allow other suspended particles to subside when the clear liquid is drawn off through a two-way cock and led into the evaporators or "effects." When all of the clear juice has been drawn off and the mud begins to show up, the clear-juice cock is closed and the other one is opened and the residual juice with impurities is conducted to a receptacle provided for this quality of the liquid. The custom in other factories is to heat the limed juice nearly to boiling (about 95° C.), shut off the heat and allow to stand until the heavier particles of the precipitated matter collect at the bottom. The clear portion of the liquid is then separated as above stated. When settling is to take place in the settling tanks the juice is heated to boiling and at once drawn into these tanks. After complete settling the clear liquid is drawn off in a manner similar to that already described. It is the custom in some factories to filter through heavy canvas bags (one folded within another) the entire volume of juice, that is, the partially clarified juice, the muddy portion being conveyed to filter presses, arranged with cloths that fit in between cast-iron plates. The juice is pumped into the filter press where these cloths retain all the solid particles. The juice defecated and clarified as above described is sometimes defe-

cated a second time, but in a very similar manner to that already described. This second defecation may take place immediately after filtration or in some instances it is after partial concentration or evaporation.

Carbonation.— See BEET SUGAR.

Super-heating.— Of recent years there has been added to the ordinary defecating process a super-heating apparatus generally known by the name of the Deming Super-heater. It is claimed that the principle of the Deming system is in converting some of the soluble into insoluble material at a temperature of from 110° to 115° C. To apply this principle three vessels, cylindrical in form, are connected with each other by a system of tubes, two of these vessels being termed absorbers and the other digester. The juice enters one of the absorbers and is pumped through it into the second. In these it is heated by exhaust steam and passes thence into the digester where it is heated with live steam to the high temperature above mentioned. As it passes out from the digester it is surrounded by an inflow of the juice on its way to the absorbers which heats it up to about 50° C. The super-heated juice, limed before being heated, is conveyed to specially constructed settling tanks that permit of a continuous inflow and outflow of juice, the impurities being collected in the conical bottom of the settling tank. This tank carries within it a large cone, the top part of which is on a level with the top of the tank, the bottom part ending at the top of the conical portion of the tank. The cone, both ends of which are open, is suspended within the tank. The lower end of the cone is of a very large diameter while the upper end has a small diameter. The principle of this contrivance consists in a downward current of juice from its entrance into the tank and an upward flow through the cone, the particles of solid matter having a greater density than the liquid and to go downward, but the upward current causes a portion of them to rise, though in their ascent they strike the sides of the cone and are returned to the bottom.

Evaporation and Crystallization.— The evaporation of sugar solutions or cane juice has for its object the concentration of the liquid to such a density as will cause the sugar to crystallize out. To accomplish this there are two methods, the "open kettle" and the vacuum pan. The open-kettle process consists in boiling the juices in open pans, either of circular or rectangular form, provided with steam coils. The heat is continued until the density indicates sufficient cooking. When a density of 22 to 36 Baumé is reached, the liquid is termed a syrup, and when the syrup is cooked to a stiff mass, a *masse cuite*. After allowing crystallization to take place in wood or iron vats, the *masse cuite* is thrown into a hogshead and the molasses percolates through a perforated bottom, or the sugar and molasses may be separated in a centrifugal machine. The sugar thus made is termed open kettle and the process is not used in the up-to-date factory.

The vacuum apparatus, a dome-shaped vessel, 5 to 10 feet in diameter, 8 to 15 feet high, provided with steam coils, is the most economical for evaporating sugar solutions, requiring only about one-third the fuel of the open kettle process and reducing to the minimum the

loss by burning or inversion. This apparatus may be arranged in "multiple effect"—two or more pans connected—or consist of one pan. More than three pans have not been found advantageous. These vessels are so controlled that the vacuum in the first is about 5, in the second 15 and in the third 25 to 27 inches, 30 representing a perfect vacuum. They are connected with a system of valves so that the juice

discharging of the pan is termed a "strike," and the product discharged, "masse cuite." This is conveyed to a mixer provided with a shaft carrying paddles or fingers that keep the sugar and adhering molasses mixed. The well-mixed masse cuite is next conveyed to a centrifugal machine, made to revolve 1,000 to 1,200 times per minute, and in its rapid motion the sugar and molasses are separated, the latter

Clarifiers.

may be drawn from the first to the second and from this to the third, from which it is drawn into a syrup tank. Exhaust steam is usually utilized for concentrating the juice, though it becomes necessary at times to use live steam. The steam enters the first and causes it to boil, and the steam generated in this is sufficient to boil the second and so on. The concentration is carried to a density of 22 to 26 Baumé or about 50 per cent water.

The syrup is drawn from the syrup tank into the vacuum strike pan until one, two or three coils are covered, and this definite quantity is heated until grains of sugar may be seen on withdrawing, with a proof stick, a sample and spreading it on a piece of glass. The formation of grain is sometimes brought about by permitting a little cold juice to enter the pan and suddenly cool it. The object here is to form a crop of "seed crystals," and the remainder of the process has for its purpose the developing or growing to a desired size. This is accomplished by continuing the boiling and adding, from time to time, small quantities of the syrup, taking care that no more grains or crystals are formed. In three to four hours the pan will be as full as is convenient to cook it and the sugar crystals as large as desired. If very large crystals are wanted, as is sometimes the case with confectioners, a "cut" strike is made, that is, one-third or half the sugar in the pan is dropped out through the bottom and the remaining portion, say one-half, is built up in the same manner as already described. On completing the boiling the second time there are not so many crystals, but they are twice as large. This process may be repeated, but it is very expensive. The principle of the strike pan is similar to that of the effects already described. The vacuum in the pan is usually 25 to 28 inches and the temperature 140° to 160° F. The cooking is continued until the concentrated mass contains 6 to 8 per cent of water. The

being thrown through very small perforations in a copper gauze basket, while the sugar remains in the basket. The product thus obtained is termed "first sugar," also "raw sugar," and usually of 96° test.

BET SUGAR.

Historical.—Sugar was discovered in the ordinary beet by Margraff, a member of the Berlin Academy of Science, in 1747, but the sugar content was very small, being from 2 per cent to 4 per cent. About half a century later, Karl Franz Archard undertook the extraction of sugar from the beet and his efforts were successful. Great interest in both Germany and France followed his investigation and by 1812 there were many factories established. Napoleon added greatly to the progress of this industry by government aid and by the establishment of sugar schools. After the new industry had become well established, it was almost obliterated by destructive wars. It was revived, however, soon in France and by 1829 a yield of 4,000 tons of sugar was made, but Germany's interest was not resumed until 1835. From these countries the industry has spread throughout Europe until the production for 1903 has been variously estimated at 5,000,000 to 6,500,000 long tons.

The first experiments with sugar-beets in the United States were made by two Philadelphians in 1830. About 10 years later David Lee Child, Northampton, Mass., attempted beet culture and the manufacture of beet sugar. He produced 1,300 pounds at a cost of 11 cents per pound. These enterprises failed and seem to have discouraged further efforts until Genert Brothers, natives of Brunswick, Germany, inaugurated a plant at Chatsworth, Ill., in 1863, and this failed seven years later. Attempt after attempt failed and it may be said that this industry was not permanently established until

between 1875-80. From this time sugar beet culture has been successfully conducted in the United States and at this writing there are 51

Filter Press.

factories distributed over 13 States, with a production of about 208,790 long tons for 1905.

Soil and its Preparation.—Sugar-beets require a mean summer temperature of about 70° F., and may, therefore, be grown in a very extensive territory in the United States, stretching from New York to California, but in this vast scope of country designated the sugar belt, there is much land that will not grow beets profitably because the soil is not adapted for such a purpose. While a great variety of soils may be suitable for growing beets, the soil best adapted for this purpose is a sandy loam with a sub-soil open so as to permit the beet to send down a tap-root and at the same time insure enough loose soil for the beets to grow well under ground, otherwise the tap-root will "sprangle" and the top of the beet will show above ground, both of which growths are deleterious to the best results.

In order that the beets may develop thoroughly, the soil must be of a loose, friable character and thoroughly prepared before planting the seed. The preparation is best effected by plowing about eight inches deep and following a sub-soiler to the depth of about seven inches and finally harrowing until all clods are broken and the soil thoroughly pulverized. If the land should be lumpy the young plants will find great difficulty in coming up, and it will be very troublesome to work or cultivate them. Thorough preparation usually destroys much weeds and grass that otherwise would interfere with the cultivation of the young beet.

Planting.—The beet seed are about the size of a small pea with a very small and rough exterior and should be put well under the earth but not deep. The seed are sown in ridges or furrows in the level ground, the latter being more general, from 14 to 18 inches apart. The seed are distributed with an implement termed a drill or seeder. The best time for planting is in the months of April and May. After planting a roller is pressed over the seed to press the soil close to them. If the rolling should make the surface too smooth and hard, another implement is passed over the ground to "roughen it up" because the wind sweeps over the fields and causes the sand to do damage to the young plants when the surface is without obstructions. Some plant seed in rows at right angles to the wind in order to avoid injury by it.

Thinning.—As soon as the young plants are well up or show four leaves thinning is begun. This consists of first bunching and then thinning to the proper number of plants to be cultivated for the crop. The thinning is performed by hand. The first part of the work is

done with a hoe which leaves a clump of beet plants about eight or nine inches apart. The thinning to a stand is then completed by selecting the best looking plant from the bunch left by the hoe and this plant is protected by placing it between the fingers with the back of the hand down, and the remainder of the small beets are removed with a sudden pull. The thinning should be done before the beets grow tall enough to become entangled with each other.

Cultivation.—The cultivation of the beet is very expensive, inasmuch as a large portion of the work must be done by hand, though of late, improved agricultural implements have reduced the expenses. The beet should be worked in some way or other, if possible, every week, with a view of preserving good tilth, the chief object being to destroy weeds and grass and conserve the moisture by forming a loose layer of soil on the surface which closes the capillary tubes in the soil through which the water evaporates. Beets should be hoed two or three times, depending upon the weeds and grass. This hoeing is partly done by a plow, but the chief part of it must be done by hand. The cultivation period usually extends over six or seven months.

Harvesting.—The harvesting is begun in different sections of the country at different periods, depending upon the climatic conditions. In some portions of California harvesting may begin in August while in sections where the temperature is not so favorable it is begun in September and October. The harvesting extends from two to four months. The beets usually indicate when they are ripe by the leaves turning yellow and drooping to the ground. The first step taken in harvesting consists in running an implement down underneath the beets so as to cut the tap-root where it is small, and, at the same time, loosen the earth around the beet so it may be readily pulled up by hand. The beet is then taken up, by hand, and with a special knife the top or "neck," as it is termed, is removed by one stroke. The top is cut off where the leaves begin to grow on the beet or just below this point. It has been found by experience that the top of the beet is very rich in non-sugars and that it is better to remove these to prevent their contamination in the process of manufacture. The beets are thrown in piles and, if they are to be sent to the factory immediately, they are not covered up, but where the beets are to be preserved some time they are put into piles of three to four feet in diameter and covered with a layer of earth varying in thickness from six to 24 inches. This latter process is termed siloing and the beets thus preserved remain in a silo until the factory is ready for them. The beets are taken to the factory in carts in which are placed nets, so arranged that they may be removed by machinery, carrying with them the entire load of beets, or the beets may be thrown directly into the cart and at the factory the cart is driven upon an elevated platform and the beets dumped out. The beets are next thrown into a large tank filled with water having a shaft, provided with fingers, so that during the process of washing the beets are kept continually agitated and brought near where fresh water is flowing into the tank. In this way all of the adhering soil is removed.

From the washing tanks the beets are taken by an elevator and carried above the diffusion battery and dropped into a slicing machine, where they are cut into very thin, narrow pieces so that when the chips fall they will not lie too compactly one upon the other. The chips are conveyed from the slicing machine to a hopper with a funnel-shaped tube and so arranged that it may be rotated or moved otherwise to fill the cells of a battery arranged in a circle or in "line." The battery consists usually of from 12 to 14 cast-iron cylindrical cells connected with each other by a system of pipes with cocks between, so that one may empty and fill without interfering with the operation of the rest. The extraction of the sugar consists in washing the chipped beets with hot water so as to remove the sugar. The battery is so operated that the water is admitted into the cell, the chips of which have been most nearly exhausted and passes out at the cell last filled. In this way the water is made to do its maximum work. When the beets have been exhausted of the sugar the bottom of the cell is opened and the beets discharged and led to a press where most of the remaining water and sugar are pressed out. The pulp cake is used in the wet condition for cattle food or it may be dried with the exhaust steam so it can be preserved for the same purpose. It may also be used to spread over the land and serve as a fertilizer.

Carbonation.—The purification of the sugar solution as above extracted consists of the application of lime, carbon dioxide and sulphur, together with settling and filtering. The use of the lime followed by that of carbon dioxide is termed carbonation. These two materials, lime and carbon dioxide, are obtained by burning limestone in a kiln constructed for that purpose at the factory. The limestone is decomposed and the lime, mixed with water, is added to the sugar solution in a quantity equal to 2 or 3 per cent. The gas is led from the lime kiln through water to wash it and admitted into a large cell from five to six feet in diameter, with a capacity of from 4,000 to 6,000 gallons. These cells are provided with steam coils so the solution may be heated. The temperature at which the carbonation is carried on is 80° to 90° C. This process of adding lime, then charging with carbonic acid gas, is repeated two or three times, depending upon the quality of the juice, but after the first treatment the juice is filtered each time before repeating the carbonation. Finally the juice is treated with sulphur dioxide, which is used to bleach the solution, and then the excess of this gas or acid is removed by the addition of lime and the juice is again treated with carbonic acid. Before filtering the juice it is allowed to settle so that the impurities may collect at the bottom of the settling tank. The clear liquid is drawn off and filtered by gravity through bags. These bags are arranged in pairs, a large bag with a diameter of three or four feet is partially folded and put into one of thicker and stronger material, with a diameter of not more than 12 to 18 inches. When the bags become filled with impurities they are steamed and washed and made ready for another operation. That portion of the solution containing the bulk of impurities is also filtered through bags which are placed in a filter press and much of the liquid removed. The press cake is scattered over the

field and used as a fertilizer. The clarified juice is treated the same as under *cane sugar*.

Molasses.—The molasses, containing 40 to 50 per cent of sugar, discharged by the centrifugal, must be treated for the sugar which it contains, though some of it in Louisiana is sold to merchants for direct consumption as table molasses, to confectioners and to glucose mixers for the preparation of glucose syrup. Generally, this molasses is recooked over and over again until all of the crystallizable sugar has been separated. The first reboiling yields "second sugar" and "second molasses," the second reboiling "third sugar" and "third molasses," etc. The reboiling may be done directly in the vacuum pan without previous treatment, in which case 5 to 10 per cent of water is evaporated, the boiled mass put into hot-room cars and kept at a temperature sufficient to maintain the *masse cuite* in rather loose or limpid state for from one to three weeks, or put into large cylindrical, slowly revolving drums provided with a proper supply of heat and kept in these for three to four days to permit crystallization to take place in motion. In either case the *masse cuite* is returned to the centrifugal and the crystals separated from the molasses. The practice at some factories is to mix the molasses with hot juice before reboiling, while others put it into eliminating pans, charge it with steam, dilute and reclarify. The second sugar may be sold to the refineries, but as it falls below the 96-test sugar (probably the most profitable grade) it is melted in the hot juice and turned out as first sugar of the test above mentioned. The second molasses is reboiled to "string proof," put into large magma tanks or hot-room cars (about five by five feet and three to four feet deep) and allowed to remain at rest from four to six months, when the crystallized mass is subjected to centrifuging. The third molasses usually contains a large portion of impurities which may make it unprofitable to further reboil it, though some work this molasses for fourth sugar. All the above grades of sugar recovered by reboiling may be worked back into a first sugar or sold to the refineries. The refuse or exhausted molasses, which amounts to from four to five gallons per ton of cane crushed and carries 25 to 40 per cent sugar, has increased very much in value in recent years, selling at 6 to 10 cents per gallon. Some of it is fed to stock and some consumed by distillers.

The molasses from the beet is worked over again and finally, in some factories, diluted, treated with powdered quicklime, which forms a sucrate of lime at low temperatures, and this sucrate is decomposed, with carbon dioxide, filtered and evaporated to obtain sugar. The final disposition of the beet molasses is also unprofitable.

Refining.—The refining of sugar consists in washing, melting, purifying, evaporating and recrystallizing. Some factories in Louisiana turn out two or three grades of refined sugar or sugar that is sold direct to the trades, but as the process used by them for refining consists chiefly in washing with water, with a solution of tin chloride, ultramarine or phosphoric acid, it is expensive because of the large portion of the sugar that is dissolved while washing in the centrifugal machine. "White clarified," "yellow clarified" and granulated

sugars are the grades referred to, but the amount of these turned out is decreasing every year. The chief difference between refining and manufacturing of sugar is in the method of clarification. This is similar in almost every respect, except in the refinery, the sugar solution, after melting and chemical treatment and filtering, is filtered through "bone black" or bone charcoal. This substance has the property of decolorizing the sugar solution which leaves these filters in an almost colorless condition. The evaporation and crystallization are carried

5 to 25 years. The sugar season is from November to February. The sugar is obtained by tapping the tree. The tapping consists in making a triangular hole in the tree, into which the sap is collected. The sap is withdrawn from the tree by means of a spile in a hole bored beneath and inclined upward to the sap receptacle. Through this spile the sap runs out and is collected in earthenware vessels. The spile is generally made of bamboo cane. The flow of sap is more rapid at night than in the day and the cooler the night the greater the flow. A

The National Cane Shredder and Mill.

out in the same way as in manufacturing. The bone charcoal soon loses its power to decolorize and is then revived by burning out the absorbed material in specially constructed retorts. The bone black will finally be exhausted of its valuable property of decolorizing and it is then sold to the fertilizer manufacturer for the manufacture of acid phosphates. The refuse molasses is used for making alcohol, for culinary purposes and to some extent for making lampblack and shoe polish.

Comparison of Cane and Beet Sugar.—When highly refined, no one can distinguish between cane and beet sugar as they are one and the same thing. Between the crude or raw beet and cane sugars there is a great difference, the latter being edible while the former is not, as it possesses a very disagreeable odor and taste. Cane sugar molasses is good for culinary purposes, beet sugar molasses is not. Cane juice contains "glucose" (reducing sugars), but beet juice does not, though the latter contains raffinose and the former does not. In Louisiana about 20 tons per acre is an average cane crop, and 15 to 16 an average beet crop in the United States. Cane is worth \$3 to \$4 per ton and beets \$4 to \$4.50. Cane costs \$30 to \$35 per acre and beets \$25 to \$30. The sucrose content will vary in Louisiana from 10 to 16 per cent, and from 12 to 18 per cent in the beets in the United States. The cost of the production of a ton of sugar is \$60 to \$75, whether from cane or beets.

Palm Sugar.—The palm-sugar industry of India is a very old one, but insignificant compared with the sugarcane industry of that country. A fair estimate places the annual production of palm sugar about 100,000 tons of 2,204.5 pounds. The sugar palms are planted on dry land, and one planting will produce sugar from

large tree will yield from 30 to 40 pounds of sugar annually and 800 trees is considered a valuable possession. The sap is collected daily, mixed with a little lime and evaporated in open vessels in a very crude way. The boiling is continued until the sap is a thick syrupy consistency or until it forms, on cooling, a solid mass. The solidifying or the last stages of evaporation is sometimes accomplished by exposure to the hot sun in that climate. The syrup is sometimes sold under the name of date-honey. This has been known for a very long time as an article of commerce.

Maple Sugar.—The variety of maple tree (*Acer barbatum*) is the one from which sugar is chiefly obtained. This tree grows wild in the forest or is cultivated in Ohio, Indiana, New York, Vermont and other northeastern States and to some extent in Canada. It is only within the last few decades that the trees have been cultivated to any great extent. A tree is 30 to 40 years old before it yields the maximum amount of sugar. A short tree with broad, spreading branches is said to produce larger yields and richer quality of sap than the tall ones with less foliage. The sugar period is from January to April. The sap begins to flow at the break-up of winter. So in one section the sap may flow as early as January while in the colder sections it may not flow before March. The flow lasts from six weeks to two months. The sap, or sugar, may be extracted from the tree in a manner similar to that of extracting it from the palm, but the triangular hole has proved to be more injurious than a small round hole. The general custom is to bore two to four holes in a tree, from two to four feet above the ground, with a three-quarter-inch augur. These holes are placed to southern

BATTERY ELECTRICALLY-DRIVEN CENTRIFUGAL MACHINES

INTERIOR CUBAN SUGAR FACTORY, SHOWING EVAPORATORS

exposure and are slightly inclined upward. In the hole is arranged, water-tight, a spile made of wood or metal on which a tin pail or wooden bucket is hung to catch the sap. The flow of sap ceases with the budding of the tree. The sap is a very pure sugar juice containing from 2 to 4 per cent of sugar, the average being about 3.5 per cent. The sap contains, in addition to the sugar, other substances in solution, some of which are of an aromatic nature and these latter give to maple sugar its splendid flavor for which it is so highly prized as a material for making table syrup. The fact that the sap is of such a high degree of purity makes the manufacture of maple sugar very simple. The sap collected in the pails is poured through a strainer into a storage tank. From this tank the sap is drawn into vats or pans, usually made of Russia iron, 2.5 feet wide and about 5 feet long. These pans are set on grate bars in brick furnaces. The fuel used is wood, one cord of which is sufficient to evaporate the water from 100 pounds of sugar. The sap is evaporated with but little or no clarification except the removal of the scum as it rises to the top during the process of boiling. The cooking is continued until the sap is of a syrupy consistency or until it begins to grain; in the former case it is sold as syrup, in the latter, it is stirred while cooling in order to produce a soft granular sugar which is put on the market and sold for making table syrup. The annual production is estimated at 15,000 to 20,000 tons.

Sorghum and Maize Sugar.—Many experiments have been made to produce sugar from sorghum, but in all the results have not been profitable. There is now very little, if any, sugar made from sorghum, though there is considerable syrup. Maize contains 9 to 12 per cent sugar, but impurities along with it have not been successfully understood and no method exists by which this sugar can be profitably extracted.

Commerce.—The sugar trade of the world has become so great that international agreement has been necessary to regulate it. European countries for quite a number of years have paid directly and indirectly bounties to sugar producers and refiners on their exports. This encouraged and abnormally developed the sugar industry in some countries and depressed it in others. The bounties placed the price of sugar so high that the poorer people in bounty-paying countries could not afford it and so low in many non-bounty-paying countries that the industry was no longer profitable to producers. A movement was started in England in 1887 to correct this evil. A convention representing Austria, Belgium, Germany, Great Britain, Italy, the Netherlands, Russia and Spain met in London, 30 Aug. 1888, and passed a resolution to guarantee "that no open or disguised bounty shall be granted on the manufacture or exportation of sugar." France would not enter the agreement because the United States would have nothing to do with it. There was no ratification of this convention, though it should have taken place 1 Aug. 1890. The bounties paid by Germany and Austria-Hungary were reported to be about \$16 per ton, and this was approximately doubled in 1896. Renewed efforts were then made to break up the bounty system and this was practically accomplished, temporarily at least, in Brussels, 1 March 1902,

after eight sittings of an international convention. This was the eighth European Sugar Bounty Conference since one held in Paris in 1862. Germany, Austria-Hungary, Belgium, Spain, France, Great Britain, Italy, the Netherlands and Sweden were represented in the convention of 1902. The following is a summary of the principal articles passed upon by that convention:

"Article 1. The high contracting parties agree, from the date of putting in force this present convention, to suppress the direct and indirect bounties which might benefit the production or export of sugar, and not to establish bounties of this kind during the whole duration of this convention. The agreement applies to confectionery, chocolate, and all analogous products, containing sugar artificially incorporated in a notable proportion; and to all advantages resulting indirectly or directly for producers from fiscal legislation, including: (a) direct bounties granted to exports; (b) and to production; (c) total or partial exemption from taxation as to any part of the output; (d) advantages derived from excessive yield; (e) and from the exaggeration of drawback; (f) and from any surtax in excess of the rate fixed by article 3.

2. Sugar factories and refineries of all kinds are to be placed in bond and worked under the continuous supervision of revenue officers; and finished sugars are to be stored in bonded warehouses.

3. The surtax is limited to a maximum of 6 francs per 100 kilogrammes (2s. 5.25d. per cwt.; or £2. 8s. 9d. per ton) for refined and assimilable sugars; and 5 francs 50 centimes per 100 kilogrammes (25s. 8d. per cwt., or £2. 4s. 8.5d. per ton) for other sugars. The surtax is the difference between the rate of the duty imposed on imported foreign sugar and the rate of duty or tax imposed on the home product. The provisions of this article do not apply to import duties on sugar imposed by countries that do not produce sugar, nor to the by-products of sugar manufacturing or sugar refining.

4. The high contracting parties agree to impose a special duty on the importation into their respective territories of sugars from countries that grant bounties either on production or export. This duty shall not be less than the amount of the bounties direct or indirect granted in the country of origin and each of the parties reserves the right to prohibit the importation of bountied sugars. In order to compute the advantages which may be derived from the imposition of an excessive surtax as specified in paragraph 5 of article 1, the surtax, at the agreed rate fixed by article 3, is deducted from such excessive surtax, and the half of the difference is considered to represent bounty. A permanent commission, instituted by article 7, will have the right, on the demand of a contracting party, to revise the rate imposed in excess.

5. The high contracting parties agree to admit, at the lowest rate of import duty, sugars of any of the contracting countries, or of any colonies or possessions, belonging to them that do not grant bounties, and to which the obligations imposed by article 8 apply.

6. Spain, Italy, and Sweden are exempt from articles 1, 2, and 3 as long as they do not export sugars.

10. The convention to come into force 1 Sept. 1903 remain five years from that date; and thenceforward (in case no state denounces it, 12 months before 1 Sept. 1908) it will remain for a year and so on from year to year. The denunciation will only have effect on the party making it.

12. The convention shall be ratified at Brussels on or before 1 Feb. 1903."

The effect of this international agreement in Europe practically shut off importations of sugar from that continent to the United States, which, however, (including its possessions, Hawaii, Porto Rico and the Philippine Islands) together with Cuba produce sufficient to supply the demand for sugar in the United States.

DUTY PER 100 POUNDS ON CUBAN SUGARS IMPORTED INTO THE UNITED STATES.

TEST	Old Rates	New Rates
75 raw.....	\$0.76	\$1.75
89 raw.....	1.152	1.05
96 raw.....	1.348	1.28
Refined.....	1.560	1.33

All Cuban sugars coming into the United States are allowed 20 per cent discount on above rates.

In 1916 a provision in the Underwood Tariff

SUGAR GROWING AND SUGAR MAKING

Law, by which sugar was eventually to go on the free list, was rescinded by Congress. The imports of sugar into the United States from 1915 to 1918 were as follows:

	Short tons
1915.....	2,710,500
1916.....	2,816,581
1917.....	2,666,373
1918.....	2,451,664

The exports during the same period were:

	Short tons
1915.....	300,552
1916.....	842,598
1917.....	634,153
1918.....	293,753

SUGAR PRODUCTION OF THE WORLD FOR FOLLOWING YEARS:

SUGAR CONSUMED IN THE UNITED STATES, 1914. (*Willett and Gray of N. Y.*)

Imported (including 510,385 tons Hawaiian, 274,149 Porto Rico, and 120,887 Philippine)	2,972,333
Domestic manufactured from imported molasses, U. S. Maple, etc.	20,200
Domestic cane	143,996
Domestic beet	624,298
Domestic total	788,494
Total annual product consumed in the United States is 84.29 pounds per capita	3,760,827

From 2,238,588 tons in 1900 the consumption of sugar in 1918 had reached 4,339,616 tons.

CONSUMPTION OF SUGAR PER CAPITA—LIGHT'S ESTIMATE FOR 1914.

	Per capita in pounds		Per capita in pounds
Germany	45.13	Netherlands	50.09
Austria	29.17	Denmark	95.37
France	43.85	Italy	11.68
Spain	14.19	Belgium	36.08
England	93.37	Turkey	21.93
Switzerland	73.55	Sweden	57.73
United States	84.29	Norway	46.64
Russia	25.43		

From 1916 to 1918 the sugar production of the United States was as follows:

	Cane	Beet	Total
	Short tons	Short tons	Short tons
1916	138,620	874,222	1,012,842
1917	310,900	820,657	1,131,557
1918	245,839	764,811	1,010,650

The large increase in sugar export during these years was due to the European War. Early in the fall of 1917 the International Sugar Committee was formed to arrange for the distribution of the available sugar in the world. The committee consisted of two members from each of the allied governments, two from the United States Food Administration being also supplemented by the head of the sugar division. This committee arranged for the purchase and distribution of all sugar to the allied countries, and as it became difficult to procure household supplies, in December 1917 the United States Senate directed an inquiry into the causes of the shortage of sugar. This was found to be due largely to consumer hoarding, and to the unusual amounts used for home preserves, also to about two-fifths of the whole quantity consumed in the United States being required for the manufacture of candy. The efficiency of the Food Administration, of the International Committee and the willing co-operation of the people served to keep down the price, to regulate the supply and to tide over the difficulty and the shortages occasioned by the indiscriminate sinkings of merchant vessels through the German submarine policy.

In 1916 the government of Panama was authorized to loan \$500,000 to plantation operators for the development of the sugar industry in that country, the loans to be repaid within 10 years; a government subsidy of one cent on every four pounds of white granulated sugar produced was also granted. In 1917, from its

development fund, Great Britain also made a grant of \$625,000 for the development of sugar-beet growing and manufacture in England.

SUGAR OF LEAD. See LEAD.

SUGAR LOAF, The, an isolated, conical hill, rising from the east bank of the Hudson River, a short distance below Garrisons. It is at the north entrance to the Highlands, about 57 miles north of New York.

SUGAR MAPLE. See MAPLE.

SUGGESTION, in psychology, a term which in its widest sense signifies an intimation, a hint, a prompting, the abrupt introduction of an idea into consciousness. It is also employed as synonymous with association. But, more specifically, it is a method of effecting belief, whether the conditions of the subject be normal, or abnormal, as in the case of hypnotism (q.v.). Under normal conditions this belief may be manifested as a conviction arrived at by reasoning, as in the case of the acceptance of a series of logical arguments; or it may be mere acquiescence in what deliberation would show to be false. Psychologists disagree as to the means by which suggestion may effect belief under abnormal conditions (for example, those of hypnotism). Lipps holds that the critical faculties of the hypnotized subject are kept in abeyance, and he is, therefore, incapable of making opposition and thereby destroying the belief. Wundt contends that the consciousness of the subject is limited, no ideas entering save those directly aroused. Such ideas are, therefore, freed from contradiction, and have a special or hyperæsthetic force. When belief persists for a time after hypnotic conditions have ceased to exist, and ultimately takes effect, such

form is called post-hypnotic suggestion. Consult Bain, 'The Senses and the Intellect' (London 1894); Bernheim, 'Suggestive Therapeutics' (trans., New York 1889); Binet, A., 'La Suggestibilité' (Paris 1900); Keatinge, W. SUHL, zool, Germany, city in Prussian judicial district Erfurt, on the southern slope of the Thuringen Forest, in the valley of the Hasel. It is situated on the State Railroad Plaue-Ritschenhausen and has two Evangelical and one Catholic church, synagogues, a city hall, upper Realschule, law court, etc. It is noted for its arms manufacturing, an ancient industry. Other manufactures are porcelain, machinery, ammunition, hardware, woodenware and toys, besides iron foundries, screw-work, etc. Its records reach back to 1330.

SUICIDE, the act of intentionally destroying one's own life, whether sane or insane—the act in itself, accompanied by the purpose, is suicide; the condition of sanity or insanity bears on the question of responsibility. In considering the causes which lead to suicide it may be well to mention the motives which deter from it. First of all is the natural love of life, which leads even condemned criminals, perhaps awaiting death by torture, to cling to the few hours or days remaining to them. This love of life is in the very nature of all living beings, and it is not always or even usually to be measured by the apparent value of existence to the individual. It is at least as strong in the Digger Indian or the Kongo negro as in the civilized and well-to-do resident of America or Europe. There is next, among the more intelligent, whether religiously inclined or not, the sense of duty to others; among the strictly religious, there is the dread of punishment beyond the grave, and statistics indicate that this is a potent and prevalent deterrent from self-destruction.

Suicide is not in itself a sign of weakness of intellect. There were periods of depression in the Revolutionary struggle when Washington was despondent almost to the point of welcoming death, and Bismarck once contemplated suicide. Napoleon, after his first overthrow, attempted suicide by taking poison. Hannibal committed suicide. Herndon, Abraham Lincoln's law partner, relates that after the death of Miss Rutledge, whom Lincoln loved, his friends watched him closely for fear that "the dark and gloomy weather might produce such a depression of spirits as to induce him to take his own life." Instances might be multiplied of the world's greatest men who either committed suicide, or attempted it, or were on the brink of it.

Although there are no statistics for comparison, yet the observations of trustworthy narrators indicate that suicide is very much more common among Asiatics than among Western nations. Arthur H. Smith, D.D., says there are parts of China in which young girls band themselves into a secret league to commit suicide within a certain time after they have

been betrothed or married, that the practice of suicide "is adopted even by children, and for causes relatively trifling. At times it appears to spread like the smallpox, and the thirst for suicide becomes virtually an epidemic." China is probably the only country in the world in which criminals are permitted, or rather directed as an act of special grace, to commit suicide. Before the Japanese adopted civilized methods suicide was also prevalent among them, the usual form being known as "hikari or seppuku" the victim disemboweling himself with knife or sword. In India vast numbers of fanatics sought death under the car of Juggernaut, and widows on the funeral pyres of their husbands, until the British authorities put a stop to these practices.

It is yet an undecided question whether education fosters the tendency to suicide or not. Thomas Garrigue Masaryk (q.v.), first President of the Czecho-Slovak Republic, when a lecturer on philosophy at Vienna in 1879, came into prominence by a study on "Suicide" as a pathological symptom of the condition of contemporary Europe. He attributed its chief cause to the decline of religious sentiment. It cannot be alleged that education has anything to do with the epidemics of suicide among Chinese women. On the other hand, it is easy to suppose, and statistics appear to support the presumption, that, other things equal, a prevalence of materialism, a disbelief in things supernatural, and consequent loss of assurance that privations and sufferings here are to be recompensed by an eternity of happiness hereafter, tend to make men tired of life and willing to anticipate by a few years their inevitable destiny. Bismarck said that "if this world were the end of all, it would not be worth the dressing and the undressing." So far, therefore, as education helps to promote materialism, it promotes suicide. At the same time it is to be remembered that such men as Tyndall and Darwin, who were avowedly in discord with accepted religious tenets, regarded it as a duty and a pleasure to live and do their share of life's work.

Professor Bailey, of the Social Science Department at Yale, after examining 10,000 cases of suicide, arrived at the following conclusions:

"Three and one-half males commit suicide to every female. From 30 to 40 is the popular suicide age, and the married are more apt to do away with themselves than the single. Among the single the maximum number of cases is between 20 and 30; among married persons between 30 and 40; among widowers, between 60 and 70, and among divorced persons the same. In this country shooting is the favorite method of suicide, poisoning being a close second. Hanging is more popular in northern Europe, and drownings in southern countries. In Maine most of the suicides hang themselves; in the cities they jump from buildings or bridges, poison themselves or turn on the gas; in the South they shoot themselves. Women drown themselves, use poison and gas. Women as a rule commit suicide in such a way as to avoid injuring their features. Young persons seem to prefer poison; the middle-aged shoot themselves and older people hang themselves. Despondency leads as the cause of suicides in America."

New York is the only American State in which attempted suicide is prosecuted as a crime. In England attempted suicide is also criminal, and the body of a person found to have committed suicide while sane is debarred from Christian burial. The feelings of relatives are almost invariably spared, however, both in America and England, by a verdict of the coroner's jury that the act was the result of insanity.

SUIDÆ, sū'i-dē, the family which includes the pigs (genus *Sus*) and other relatives, characterized by the rooting snout, bristly coat, large and low hind hoofs, peculiar dentition and other common features. See SWINE or HOGS.

SUIDAS, sū'i-dās, Greek lexicographer of the 10th or 11th century. He wrote a lexicon which forms a kind of cyclopædia and dictionary, giving explanations of words, and notices of persons, places, etc., in alphabetical order.

SUIR, shoor, Ireland, a river which rises in the Slieve-Bloom Mountains, in the north of Tipperary; flows in an irregular course, forming the boundary between Tipperary, Waterford and Kilkenny; passes the towns of Clonmel and Carrick; and after a course of about 80 miles unites with the Barrow to form the estuary of Waterford harbor. It is navigable by vessels of 500 tons to Waterford, and by large barges to Clonmel.

SUKA-SAPTATI, soo'ka-sāp'ta-tē, Sanskrit, 'Seventy (Tales) of a Parrot,' taken from Nakshabī's 'Tūti Nāma,' or Parrot Book (A.D. 1320). It is the Persian story of a merchant leaving his young wife for a 70 days' journey. He commends her always to obtain advice by consulting his wonderful trained parrot in every emergency. The bird's advice is solicited early when the wife has temptation thrown her way and the parrot temporized with her by telling a story which so pleased and flattered her that she spent the night listening to the absorbing relation. And with the sunrise the advice was declared by the parrot to be contingent upon what happened under the conditions that prevailed in a story which he would recite the next evening. The following night's story aroused equal interest in the wife, but is indissolubly connected with another night's story which the parrot recites so entertainingly that in this manner the luring continuations of the tales keep the tempted wife from erring the remaining evenings of the 70 days' absence of the merchant. And the husband returns to find his wife saved from dishonor. Consult Schmidt, 'Über die Suka-Saptati' (Halle 1898); MacDonnell, A. A., 'History of Sanskrit Literature' (London 1913); Wortham's

'Enchanted Parrot' (London 1911) contains several of these parrot stories.

SUKHAVATI, sook-hā'va-tē, Sanskrit, blissful. The Mahayana Buddhist's Land of Bliss, the heaven he reaches in the course of his transmigrations if a believer in Amitabha Buddha who presides over it. Gods and men are here on a perfect equality, earthly ills do not exist and the seasons and days are not. Elevation to this heaven is by absolute trust in the presiding deity. Consult Suzuki, D. F., 'Outlines of Mahāyana Buddhism' (London 1907).

SULEIMAN PASHA, soo-lā-mān' pāsh'ā, Turkish military officer: b. 1840; d. 11 Aug. 1892. After entering the army he was made a major in 1867; colonel in 1873, and general of brigade in 1874. In 1876 he distinguished himself as commander against the Servians. When the Russians declared war (1877) against Turkey, Suleiman checked them at Eski Zagra, and destroyed his army in heroic but vain attempts to force them from the Shipka Pass. In October he was appointed commander-in-chief of the Army of the Danube, but failed to accomplish anything, retreated behind the Balkans, and suffered defeat near Philippopolis (January 1878). Brought before a court-martial, he was condemned to be degraded and kept in a fortress prison for 15 years. The Sultan, however, pardoned him.

SULIMAN (soo-lē-mān') **MOUNTAINS**, India, a range of the Northwest Frontier Province, near the Afghanistan frontier. The range consists of several parallel ridges, of which the most westerly form the water-parting between the rivers flowing east to the Indus and those flowing westward through Afghanistan. It extends north and south from the Safed Koh to about the Bolan Pass, and is crossed by many passes, of which the chief are those of Kuram, Gumal and Sangar. The highest peak, Takht-i-Suliman, or "Suliman's Seat," has two summits, 11,295 and 11,070 feet high respectively. These mountains are generally rocky and precipitous, and their sides are completely bare of trees. The passes through them are generally held by independent tribes in alliance with the British.

SULINA, soo-lē'nā, Rumania, the central arm of the Danube delta. In 1902 extensive improvements were completed which rendered it a navigable ship canal, and the commercial entrance to the Danube. At its mouth is the town of Sulina, which is a free port with a population of about 5,611, and an extensive transit trade.

SULIOTS, soo'li-ōtz, a mixed people of Arnaout and Greek descent, who, to escape the tyranny of the Turks in the 17th century, settled in the mountains near Parga, occupying a wild valley enclosed on three sides by almost inaccessible mountains, and accessible on the fourth only by a narrow defile. Here their numbers had increased toward the end of the 18th century to 10,000, their chief village being called Suli. Their government was republican. Old customs were followed instead of written laws. They were distinguished for the simplicity of their manners and for their bravery. Their mother-tongue was the Albanian, but they also spoke Greek. They lived partly by

the rearing of cattle and the chase, and partly by plunder. When, after a struggle of several years, Ali, pasha of Yanina, had rather reduced them to despair than conquered them (1803), most of them abandoned their country. But when Ali found himself hard pressed by the Turks and deserted by the Albanians, he recalled the Suliots to his assistance. When the Greek war of independence broke out, the Suliots joined the Greeks. Suli was besieged by the Turks, and in September 1822 was compelled by famine to surrender. Three thousand Suliots then embarked in British ships for Cephalonia; the rest dispersed themselves in the mountains. The corps of 500 men, raised and equipped by Lord Byron at his own expense, was composed of Suliots, for whom he had a great admiration. See BOZZARIS.

SULLA, *sul'a*, **Lucius Cornelius**, Roman dictator: b. 138 B.C.; d. 78 B.C. He received a good education, but was notorious from his youth upward for his excessive dissipation and debauchery. He served with distinction under Marius in the Jugurthine (107 B.C.) and Cimbrian (104-2) wars, and in 93 was chosen praetor. For his services in the Social war (90-88) he was appointed consul (88 B.C.), and the province of Asia, with the conduct of the war against Mithridates, fell to his lot. Marius was also ambitious of his command, and resorted to acts of violence to carry his point, by which Sulla was compelled to escape from Rome. But Sulla re-entered the city at the head of his army, drove Marius to Africa, and then sailed for Greece at the beginning of 87 B.C. He expelled the armies of Mithridates from Europe (86), crossed into Asia (84) and was everywhere victorious, gaining plenty of wealth for himself and his soldiers, and forcing Mithridates to conclude a peace. Marius had died in 86 B.C., after proscribing Sulla and confiscating his property, but the party of Marius was still strong. Sulla now hastened to Italy, and landed at Brundisium with 40,000 men 83 B.C. He was joined by many of his friends who had been banished from Rome. He gained four battles over the Roman forces in person, and defeated a Samnite army under Telesinus. He entered the city victorious in 82, and immediately put to death between 6,000 and 7,000 prisoners of war in the Circus. Rome and all the provinces of Italy were filled with the most revolting scenes of cruelty. After satisfying his vengeance by the murder or proscription of thousands he caused himself to be named dictator for an indefinite period (81 B.C.). He ruled without restraint, repealed and made laws, abolished the tribuneship, and settled his veterans in various parts of Italy. In 79 B.C. he laid down his dictatorship.

SULLINS (*sul'inz*) **COLLEGE**, a college for women, located at Bristol, on the State line between Virginia and Tennessee. It was founded in 1870 by David Sullins, a minister of the Methodist Episcopal Church, South, and is under the control of the Holston Conference of that church. It has an elementary, a preparatory and a collegiate department. The collegiate course leads to the degree of A.B.; courses in pedagogy are offered; there is also a business course of one year, a School of Expression and Physical Culture, a School of Art and a Department of Music. Physical exercise

is encouraged, and a course in light gymnastics is required of all students. The college has a beautiful and healthful situation; the grounds and buildings are valued at \$75,000. The students average annually 230, and the faculty numbers 22.

SULLIVAN, **Sir Arthur Seymour**, English composer: b. London, 13 May 1842; d. 22 Nov. 1900. His father was a military bandmaster, and taught his son before nine years of age to play every wind-instrument used in the band, thus laying the foundation of the wide orchestral knowledge afterward displayed by Sir Arthur. Endowed with a fine treble voice he became a choir-boy at the Chapel Royal; in 1856 gained the Mendelssohn scholarship of the Royal Academy of Music, where he continued his musical education; and in 1858 went to Leipzig, completing his studies with Moscheles, Hauptmann, and other famous instructors of that period. On his return to England in 1862 he at once attracted attention by his music to Shakespeare's 'Tempest.' His serious works include the oratorios 'Prodigal Son,' and 'Light of the World,' anthems, hymns, numerous favorite songs, etc.; but his most popular compositions are the Savoy series of burlesque operettas which he produced in conjunction with W. S. Gilbert. Among the most popular of these are 'H. M. S. Pinafore' (1878); 'Pirates of Penzance' (1880); 'Patience' (1881); 'Iolanthe' (1882); 'Mikado' (1885); 'The Yeoman of the Guard' (1888), and the 'Gondoliers' (1889). In 1886 he set to music an arrangement of Longfellow's 'Golden Legend,' which is one of his finest compositions, and in 1891 produced his grand opera 'Ivanhoe,' a masterly work which did not win the success its merits deserved. He was knighted in 1883. Consult Cellier and Bridgman, 'Gilbert and Sullivan and their Operas' (Boston 1914); Findon, B. W., 'Sir A. Sullivan, His Life and Music' (London 1903); Lawrence, A., 'Sir A. Sullivan, Life-story, Letters and Reminiscences' (London 1900); Wyndham, H. S., 'Arthur Sullivan' (London 1904).

SULLIVAN, **John**, American military officer: b. Berwick, Me., 17 Feb. 1740; d. 1795. He received, in 1772, the commission of major, and in 1775 that of brigadier-general. The next year he was sent to Canada, and on the death of General Thomas, the command of the army devolved on him. In this year he was promoted to the rank of major-general, and was soon after captured by the British in the battle on Long Island. He commanded a division of the army at the battles of Trenton, Brandywine and Germantown; and was the sole commander of an expedition to the island of Newport, which failed through want of co-operation from the French fleet. In 1779 he commanded an expedition against the Indians. He was afterward a member of Congress, and for three years president of New Hampshire. In 1789 he was appointed a judge of the District Court and continued in that office till his death.

SULLIVAN, **John Lawrence**, American pugilist: b. Boston, Mass., 15 Oct. 1858; d. West Abington, Mass., 2 Feb. 1918. This remarkable man, who has not inaptly been described as "the last of the gladiators," was

the principal exponent of a science that seems to have passed out of vogue. Endowed with herculean strength and physique, together with the necessary concomitants of courage and pugnacity, his picturesque figure and exciting career were typical of the ancient gladiator. At 19 he fought his first battle on the stage of a Boston theatre when he knocked out a pugilist named Scannell, who had challenged any man in the audience. Hereafter he adopted fighting as his profession. His feats of strength earned him the sobriquet of "the Boston Strong Boy," and in 1878 he made his debut as a professional by knocking out "Cockney" Woods. On 7 Feb. 1882 he met and defeated Paddy Ryan in a bare-knuckle fight at Mississippi City for \$5,000 a side and the championship of America. Sullivan's trainer, Billy Madden, is said to have coined the now well-known phrase "knockout" on this occasion. His next important fight was in 1888, with "Charlie" Mitchell (q.v.), ending as a draw at the 39th round, and on 8 July 1889 he fought his greatest battle, that with Jake Kilrain, at Richburg, Miss. This was the last championship fight in America under London Prize Ring rules and gave Sullivan the victory in 75 rounds. His contest with Mitchell proved that the only method likely to succeed against him was that of agility in keeping beyond the range of his powerful right-hand blows, and it was by adopting these tactics that James J. Corbett deprived Sullivan of the championship in 21 rounds at New Orleans on 7 Sept. 1892. This was his last contest, after being champion of the world for 12 years. His bohemian style of life had injured his magnificent constitution. In his later days he became an ardent advocate of temperance and retired to the farm where he died.

SULLIVAN, Sir William Wilfrid, Canadian statesman: b. New London, Prince Edward Island, 1843. He was educated at Saint Dunstan's College, and was called to the bar in 1867. He was a member of the provincial legislature, elected as a conservative, till 1889, becoming premier and attorney-general (1879-89), and being raised in the latter year to chief justice. Knighthood was conferred on him in 1914.

SULLIVAN, Ill., city and capital of Moultrie County, on the Wabash, the Chicago and Eastern Illinois and the Illinois Central railroads. It contains the Illinois Masonic Home and hospital, and its industrial establishments consist of a planing mill, flour mill, machine shops, grain elevators, etc. Pop. 2,621.

SULLIVAN, Ind., city and capital of Sullivan County, on the Evansville and Terre Haute and the Illinois Central, the Chicago and Eastern Illinois and the Chicago, Terre Haute and Southwestern railroads. It is two miles west of Terre Haute, and has coal mining and other industries, and contains a Carnegie library, Elks' Home, etc. Pop. 4,115.

SULLIVAN'S ISLAND, at the north entrance to Charleston Harbor, South Carolina, six miles out from Charleston. It is separated from the mainland by a tidal channel. On this island is the well-known Fort Moultrie (q.v.). The island is about six miles long. It is a

favorite resort for sea-bathing. Steam ferry-boats ply regularly between the city and the island.

SULLY, sül'i, Alfred, American military officer: b. Philadelphia, Pa., 1821; d. Fort Vancouver, Wash., 17 April 1879. He was graduated at the United States Military Academy in 1841 and assigned to the Second infantry, with which he took part in the Seminole War and served in the war with Mexico in 1846-47. In 1861-62 he won distinction in the battles of Fair Oaks and Malvern Hill; was promoted brigadier-general of volunteers in October 1862. In 1863 he was given command of the Department of Dakota and greatly distinguished himself in his campaigns against hostile Indians. At the close of the war he was brevetted major-general of volunteers, and brigadier-general, United States army, for gallantry during the war, and was promoted colonel of the 10th infantry in 1872.

SULLY, James, English philosopher: b. Somerset, 3 March 1842. He was educated in the Independent College at Taunton and in Regent's Park College, London. He afterward studied at the universities of Göttingen and Berlin, and in 1871 began to contribute to newspapers and reviews. From 1892 to 1903 he was Grote professor of the philosophy of mind and logic in University College, London, and also held the post of lecturer on education at the College of Preceptors. He published 'Sensation and Intuition' (1874); 'Pessimism: a History and a Criticism' (1877), containing acute criticism of Schopenhauer and Von Hartmann; 'Illusions' (1881), in the International Scientific Series; 'Outlines of Psychology,' with especial reference to the theory of education (1884); 'The Teacher's Handbook of Psychology' (1886), based upon the preceding work; 'The Human Mind' (1892); 'Studies of Childhood' (1895); 'Children's Ways' (1897); 'Essay on Laughter: Its Forms, its Causes, its Development and its Value' (1902); 'Italian Travel Sketches' (1912).

SULLY, sül'i, Thomas, American artist: b. England, 1783; d. Philadelphia, 5 Nov. 1872. He came to the United States with his parents, who were actors, in 1792; studied painting in Charleston, S. C., and Richmond, Va., and in 1806 removed to New York. In 1809 he went to London to complete his studies. Two years later he returned and settled in Philadelphia. His reputation as one of the leading American portrait painters is founded on numerous works, the best known of which are the full-length portraits of Dr. Benjamin Rush, Commodore Decatur, Thomas Jefferson and Lafayette. The Boston Museum possesses his celebrated picture of 'Washington Crossing the Delaware.'

SULLY-PRUDHOMME, sü-lë prû-dôm, René François Armand, French poet: b. Paris, 16 May 1839; d. Chatenay, 6 Sept. 1907. He studied law, but turned entirely to letters; published his first verses 'Stances et Poèmes,' in 1865, and gained praise from Sainte-Beuve, and followed up his success by several volumes, grave in manner, with finished versification and subtle in thought. Pre-eminently a thinker, he attempted a poetic treatment of abstract themes in the didactic 'La Justice' (1878) and 'Le Bonheur' (1888). He also made a metrical

rendering of Book I of Lucretius' 'De Rerum Natura,' accurate enough, but somewhat ragged (new ed., 1886), and published in prose, 'Réflexions sur l'Art des Vers' (1892), and a noteworthy article on Pascal in the *Revue des Deux Mondes* (1895). In 1881 he was chosen to the Academy and in 1882-88 his 'Œuvres Complètes' appeared. Among the titles of several individual volumes are 'Les Épreuves' (1866); 'Les Solitudes' (1869); 'Les Destins' (1872). In 1901 he won the Nobel prize for literature.

SULPHANILIC ACID, Para-Aminobenzene Sulphonic Acid, $\text{C}_6\text{H}_4\left\langle\begin{smallmatrix} \text{NH}_2 \\ \text{SO}_3\text{H} \end{smallmatrix}\right\rangle$, or, $\text{C}_6\text{H}_4\left\langle\begin{smallmatrix} \text{NH}_2 \\ \text{SO}_3 \end{smallmatrix}\right\rangle$, was first prepared by Gerhardt

in 1845. It is usually obtained by heating aniline with fuming sulphuric acid at 180°C ., for several hours. Upon pouring the reaction mixture into cold water a fairly pure product is obtained, which may be further purified by converting into the sodium salt and by treating the latter with animal charcoal. Sulphanilic acid has also been prepared by a patented process (Ger. 205150), which consists in heating chlor-benzene-p. sulphonic acid with ammonia under pressure in the presence of cupric chloride. Under this treatment the chlorine atom is readily replaced by the NH_2 group. Sulphanilic acid crystallizes from hot water in plates with one molecule of water of crystallization. It has no definite melting point; upon heating it decomposes between 280° - 300°C . One part of the acid dissolves in 112 parts of water at 15°C . Upon oxidation with manganese dioxide and sulphuric acid it forms quinone. Fused with caustic potash it yields aniline and with bromine water it is readily converted into tribromaniline.

Sulphanilic acid is of special importance as an intermediate in the manufacture of azo-dyes. When its sodium salt is treated with sodium nitrite in the presence of sulphuric acid, diazobenzene sulphonic acid is formed, which may be readily coupled with a number of reagents forming important azo-dyes. With phenol the diazo compound forms Tropaeolin Y. With resorcin it yields Resorcin Yellow. With dimethyl aniline it forms Helianthine, the alkaline salt of which is the well-known indicator Methyl Orange. With alpha-naphthol the diazo compound forms Orange I, one of the seven food colors, and with beta-naphthol it forms Orange II. Sulphanilic acid has also been used for the manufacture of Resorcin Brown, Azofuchsine G, Hessian Brown MM, Benzo-Brown G, Columbia Green, and Conogo Brown G.

Lehigh University.

SULPHIDE COPPER ORES. The principal sulphide copper ores of the United States are chalcocite or copper glance (Cu_2S), containing 79.8 per cent of metallic copper; enargite (Cu_3AsS_4), 48.3 per cent; covellite (CuS), 66.4 per cent; chalcopyrite or copper pyrites (CuFeS_2), 34.5 per cent; bornite or peacock ore (Cu_5FeS_4), 50 to 70 per cent. Other sulphide copper ores of less commercial importance because in small quantity are: tetrahedrite ($4\text{Cu}_2\text{S}\cdot\text{Sb}_2\text{S}_3$), 25 to 40 per cent metallic copper; tennantite ($4\text{Cu}_2\text{S}\cdot\text{As}_2\text{S}_3$), 57.5 per cent;

chalcantite ($\text{CuSO}_4\cdot 5\text{H}_2\text{O}$), 25.4 per cent; chalmersite (CuFe_2S_3); cubanite (CuFe_2S_4); and the rare carrollite (CuCo_2S_4). As all these minerals show evidences of recent formation they are regarded as probably concentrations from pyrite beds. Chalcopyrite and bornite seem to have been the primary deposits from which the others have been derived. In most localities the ores are of such low grade that water concentration is necessary before smelting. Nevertheless the sulphide ores must be regarded as the most important of all ores of copper as they supply much the larger part of the metal sold in the world's markets.

The most important sulphide mining districts are Butte, Mont.; Bisbee, Ariz.; Bingham Canyon, Utah; Ely, Nev.; Ducktown, Tenn., and Shasta County, Cal. In the Butte district of Montana, the greatest copper producing territory in the world, the ores are mainly secondary sulphides in fissure veins. More than half are chalcocite and considerably less than half enargite, although the proportion of the latter is increasing with the depth. With these are bornite, covellite and cupiferous pyrite. The primary ores of this region were chalcopyrite and pyrite. At deep levels (2,800 feet) are found masses of primary chalcocite, far below the zone of secondary enrichment. In Arizona three-fourths of the copper ores are sulphides. At Bisbee occur large masses of primary ore, but in the other districts the replacement of the original chalcopyrite and pyrite with chalcocite has been practically complete. In the Globe district the primary ores—pyrite and chalcopyrite—occur in commercial quantities, but the largest output is from the secondary deposits of chalcocite on deeper sulphides. In the Jerome district the important ore is primary chalcopyrite. At Bingham, Utah, there are large replacement deposits of pyrite, chalcopyrite, sphalerite and chalcocite, with some bornite and primary enargite. In some places covellite and tetrahedrite are found with chalcopyrite. At Ely, Nev., there are extensive replacements of chalcopyrite by chalcocite, and also bodies of chalcopyrite enriched with chalcocite. At Ducktown, Tenn., the primary ores are pyrite, chalcopyrite and bornite. The paying ore bodies are secondary chalcocite, with secondary chalcopyrite at a lower level—with some covellite, bornite and chalcantite. In the Shasta copper belt of California large bodies of massive sulphides are found along the borders and within the areas of eruptive rocks, chiefly pyrite and chalcopyrite, with chalcocite below; and some bornite and tetrahedrite.

Examples of replacement of pyrite by chalcocite are found in every important district producing sulphides. The pyrite first becomes coated with a black stain; later the chalcocite penetrates it along cracks and fissures, and finally the whole becomes a mass of sooty black chalcocite.

At some of the sulphide mines all of the ore goes directly to the roasting furnace. At other mines where the ore is of lower grade it is first concentrated by mechanical means—screening, crushing and separating on jigging tables. The flotation process (q.v.) is particularly adapted to the concentration of sulphide ores, which are difficult to wet, and hence have a greater tendency to float, a tendency which

is largely increased by treating them with oil. At other mines the ore is crushed to a diameter of one-fourth of an inch and leached with a solution of sulphuric acid, made on the spot by the burning of pyrite.

Treatment of Concentrates.—These are usually roasted in mechanical roasters, the most approved type being the improved McDougal furnace. The chemical action is the change from the sulphide condition to the oxide. The iron sulphide present also becomes the protoxide and then the sesquioxide. After roasting to, say, $7\frac{1}{2}$ per cent sulphur content, the product is fused in reverberatory furnaces to form matte running usually 40 per cent to 50 per cent copper, and slag running 0.30 per cent to 0.67 per cent copper, which is usually thrown away as valueless. The matte is, as a rule, converted without being allowed to cool between reverberatories and converters.

Treatment of Lump Ore, Etc.—Ores are treated in blast furnaces, using coke as fuel in greater or less amounts, according to the smaller or larger content of pyrite in the ore. The smelting generally practised in the United States is known as the "semi-pyritic" and it takes advantage of the fuel value of the sulphides in the ore, as far as possible.

The fines are briquetted before charging them into the blast furnace, wherever suitable bonding material is obtainable, at low cost;—for example, slimes from the water concentration of the copper ores. In some localities the fines are sintered and in others nodulized to prepare them for blast furnace treatment. The resulting matte and slag are treated in ways similar to those obtaining in reverberatory smelting.

Converting.—The most common type of converter is the "trough" converter, with rows of tuyeres along the back, entering the charge a few inches above the bottom. The linings are usually made of magnesite brick. The products of the converter are sulphurous gases which escape through the flues and stacks; slag which is returned to the blast, or reverberatory furnaces; and "blister" or converter copper, which is either cast in pigs or anodes for electrolytic refining and the extraction of gold and silver values. For refining, see **ELECTRO-CHEMICAL INDUSTRIES**.

The improvements in recent years in the sulphide smelting have consisted in the adoption of mechanical roasters, the arrangement of the furnaces so that the product can be transferred from one department to another with minimum loss of heat and with the least possible handling, and the enlargement of the smelting units; for example, some reverberatory smelting furnaces now have a hearth measurement of 25×146 feet, and a smelting capacity of over 1,000 tons daily. Blast furnaces may now be built of unlimited length, the largest measuring 56 inches by 87 feet at the tuyeres with a daily capacity of 3,000 tons of charge; converters holding over 100 tons of matte have been built, but the most economical size seems to be of a capacity of about 80 tons. Other economical practices are the handling of slag, ashes, and other waste products in sluice boxes by water; the handling of materials generally by machinery; and the saving of waste heat from smelting furnaces; all the modern appliances for handling materials, water, steam,

electricity and compressed air are called upon to assist in the operation of modern plants. Fuel oil and pulverized coal have been applied to reverberatory furnaces with great success in recent years. Developments looked for in the near future are the substitution of electric furnaces for the blast furnaces and an extension of the hydro-metallurgical processes.

The industry is prosecuted on a gigantic scale in the United States; the amount of capital invested is enormous, the average cost of a sulphide smelting establishment being \$1,000 for each ton of ore treated daily. The largest plant constructed to date (1919) is the Anaconda Reduction Works at Anaconda, Mont., having a daily capacity of 18,000 tons of ore and producing about 15 per cent of the world's output of copper. A brief description of this smelter will give a general idea of the operation of a modern copper sulphide smelting plant, and the immense size of the plant. The copper ores, delivered on the "high line" by the Butte, Anaconda and Pacific Railway, are first enriched by mechanical concentration. In this process the useless part of the ore is separated from the valuable portion by making use of differences in specific gravity, the useless part being sluiced to the dump and the 3 per cent of copper in the ore becoming 8 per cent in the concentrated product.

The fine portion of this product is roasted, to remove 80 per cent of its sulphur, and is then smelted in reverberatory furnaces. The coarser portion goes to the blast furnaces, in which the burning off of 60 per cent of the sulphur and the melting of the charge are done in one operation. The reverberatories and blast furnaces produce matte (the copper content of which ranges from 40 to 50 per cent), and make slag as a waste product which is sluiced to the dump. The matte is treated in converters, which deliver an impure copper. The last stage is reached in the refining furnaces, which turn out the commercially pure metal; and this is shipped to the company's electrolytic plants at Great Falls, Mont., and Perth Amboy, N. J., where the silver and the small amount of gold are separated. The metals are then marketed.

The zinc ore is increased from an assay of 12 per cent zinc to 32 per cent by mechanical concentration. The metallurgical treatment of this concentrate is conducted at the company's plant in Great Falls, except as noted under the subject of roasting.

E. P. MATHEWSON.

SULPHIDES, compounds of sulphur with some other element, constitute a large and important group of minerals. Pyrite and Marcasite, of the same composition (FeS_2) but differing in crystal form are probably the most abundant and widely disseminated sulphides. They are of no value as ores of iron but are largely used in the manufacture of sulphuric

acid. The sulphides are the most important group of ore minerals and include the lead ore Galena (PbS), the zinc ore Sphalerite (ZnS), the silver ore Argentite (Ag₂S), the copper ores Chalcocite (Cu₂S), and Chalcopyrite (CuFeS₂), the quicksilver ore Cinnabar (HgS), the magnetic iron sulphide Pyrrhotite (FeS) which is often nickel bearing, and many other ores of lesser importance. See PYRITE; GALENA.

SULPHINDIGOTIC ACID, or **INDIGOTIN DISULPHONIC ACID**, an amorphous blue solid substance, having the chemical formula $C_{16}H_8N_2O_2(SO_3H)_2$, and prepared by heating indigo with fuming sulphuric acid. It is readily soluble in water and in alcohol. It has acid properties, and its salts are sparingly soluble in water. The sodium salt is known commercially as indigo extract, indigo-carmin, or soluble indigo. As the color is not fast it is now seldom used as a dyestuff.

SULPHINIC ACIDS, organic acids containing the group SO(OH), with the sulphur united to a carbon atom. Methane sulphinic acid, for example, which is prepared by the action of sulphur dioxide upon zinc-methyl, $Zn(CH_3)_2$, has the formula $CH_3SO(OH)$. The sulphinic acids, in general, may be prepared by the action of zinc dust upon ethereal or alcoholic solutions of the chlorides of the sulphonic acids; and the sulphinic acids of the fatty series may be prepared (as in the foregoing example) by the action of the dioxide or trioxide of sulphur upon zinc alkyls. They oxidize into sulphonic acids (q.v.).

SULPHITES. See SULPHUROUS ACID.

SULPHOCYANIC ACID, or **THIOCYANIC ACID**, a substance having the chemical formula HSCN for the normal form. The acid form, HNCS, has not been isolated but its ethereal salts have been recognized, and possessing powerful acid properties. The hydrogen that it contains can be replaced by bases, with the formation of a series of salts known as sulphocyanides or thiocyanates, most of which are soluble in water. Potassium sulphocyanide, KSCN, may be prepared by the direct combination of sulphur with cyanide of potassium, KCN. The ammonium salt $(NH_4)SCN$, is obtained (together with ammonium sulphide) when carbon disulphide is heated with an alcoholic solution of ammonia. The ammonium salt is found abundantly in gashouse liquor. The sulphocyanides of the heavy metals are usually prepared by fusing them with the sulphides of the alkaline metals, preferably potassium, by double decomposition. The free acid may be prepared by heating small quantities of mercury sulphocyanide in a stream of dry sulphuretted hydrogen gas; but its preparation in this manner is more or less dangerous, as it is often attended by explosions of some violence. A dilute solution may be obtained by distilling an excess of a sulphocyanide with dilute sulphuric acid. The pure acid is a colorless liquid at ordinary temperatures, with a strong characteristic smell. By the action of a freezing mixture of snow and salt, it may be obtained in the form of crystals. When heated it decomposes into hydrocyanic acid (HCN) and persulphocyanic acid $(H_2C_2N_2S_2)$. Dilute aqueous solutions of sulphocyanic acid are stable at ordinary temperatures, but the anhy-

drous acid gradually passes into the polymeric substance known as disulphocyanic acid, $H_2S_2C_2N_2$. Disulphocyanic acid, when pure and freshly prepared, is a waxy yellow substance, nearly insoluble in water. It hardens with age, and upon the application of heat it is converted into ordinary sulphocyanic acid. Trisulphocyanic acid is not known except through its methylic salt $(Me_3S_3C_3H_3)$, obtained (with methyl triocarbamide) by heating methyl sulphocyanide to 356° F.

SULPHONAL, Diethylsulphone Dimethylmethane, $CH_3 \begin{array}{c} \diagup \\ C \\ \diagdown \end{array} \begin{array}{c} SO_2C_2H_5 \\ SO_2C_2H_5 \end{array}$, was discovered by

Baumann in 1886, and introduced into medicine as an active hypnotic in 1888. It is prepared by the condensation of a mixture of ethylmercaptan and acetone in the presence of hydrochloric acid or zinc chloride. Under these conditions dimethyl diethyl mercaptole, $CH_3 \begin{array}{c} \diagup \\ C \\ \diagdown \end{array} SC_2H_5$, is obtained, which yields sulpho-

nal upon oxidation with potassium permanganate. On account of the difficulty experienced in handling ethyl mercaptan, the use of sodium thiosulphonate $C_2H_5S_2SO_3Na$, in the presence of hydrochloric acid, has been suggested. This compound will also yield a mercaptole with acetone, and from mercaptole sulphonial may be obtained by oxidation.

Sulphonial crystallizes in colorless prisms. It melts at 125°–126° C., and boils without decomposition at 300° C. It dissolves in 15 parts of boiling water, and in 500 parts of water at 15° C., but is freely soluble in boiling chloroform, alcohol, acetone, benzene and toluene. In doses of 15–30 grains sulphonial will usually induce sleep, although the time required for its action shows wide individual variations. It has been classed among the safe and dependable hypnotics, as it induces quiet sleep with no marked after-effects, but its continued use has in some instances developed chronic poisoning with fatal consequences.

The hypnotic action of sulphonial has been traced to the ethyl groups present in its molecular structure. It has been definitely shown that of the compounds closely related to sulphonial those containing no ethyl groups are not physiologically active. Thus dimethyl-

sulphone dimethyl methane, $CH_3 \begin{array}{c} \diagup \\ C \\ \diagdown \end{array} \begin{array}{c} SO_2CH_3 \\ SO_2CH_3 \end{array}$, has no hypnotic action. On the other hand

trional, $CH_3 \begin{array}{c} \diagup \\ C \\ \diagdown \end{array} \begin{array}{c} SO_2C_2H_5 \\ SO_2C_2H_5 \end{array}$, is more active than

sulphonial, and tetronal, $C_2H_5 \begin{array}{c} \diagup \\ C \\ \diagdown \end{array} \begin{array}{c} SO_2C_2H_5 \\ SO_2C_2H_5 \end{array}$, is even more active than trional.

V. S. BABASINIAN,
Lehigh University.

SULPHONIC ACIDS, a series of acids, both organic and inorganic, distinguished by containing the monovalent radical, SO_3OH , also written, SO_3H . The inorganic members of the group may be regarded as derived from $SO_3OH.H$ by replacing the final H by a monovalent atom or radical, such as chlorine; or, more generally, from

n molecules of $\text{SO}_2\text{OH.H}$, by replacing the n final H atoms by a single n -valent atom or radical. Chlorosulphonic acid, $\text{Cl}(\text{SO}_2\text{OH})$, is an example of such an acid. It may be prepared by the direct combination of sulphur trioxide, SO_3 , with hydrochloric acid, and also in various other ways. The number of hydrogen atoms replaced depends on the strength of the acid used and on the temperature at which the action is carried on. In organic sulphonic acids, the SO_2OH group is joined, by means of its own sulphur atom, to a carbon atom in some organic base. There arise from such combination two classes of sulphonic acids, the aliphatic and the aromatic. Only the latter series is of importance in the arts. The sulphonic acids of aromatic compounds play an important part in the coal-tar color industry, and they may be readily prepared by digesting aromatic compounds with either sulphur trioxide, sulphuric acid, or chlorosulphonic acid. The aromatic sulphonic acids are usually prepared by boiling the sulphonation product with an excess of calcium carbonate, or, preferably, barium carbonate. The barium sulphate precipitated is separated out by filtering. The filtrate contains the barium (or calcium) salt of the sulphonic acid. To this filtrate sulphuric acid is added drop by drop until no more precipitate forms. The solution is again filtered, and the filtrate evaporated to dryness, the acid appearing either as a syrupy liquid or in crystals, according to its constitution. If calcium carbonate has been used traces of it will remain in the acid, and must be removed by adding alcohol, filtering, and evaporating the alcohol with gentle heat. Where the result contains two sulphonic acids they are usually separated by conversion into sulphonic chlorides by the addition of phosphorus pentachloride (or oxychloride) and crystallized—when they assume their distinctive forms.

The aromatic sulphonic acids are strongly acid in reaction, and are generally highly soluble in water, the crystalline forms as a rule being hygroscopic. When heated, they decompose gradually without melting. They are manufactured in large quantity to be converted into phenols—readily accomplished by fusion with caustic alkalis. Consult Benedikt, 'Chemistry of the Coal Tar Colors.'

SULPHOVINIC ACID, or ETHYL-SULPHURIC ACID, in chemistry, mono-ethyl phate, $\text{C}_2\text{H}_5\text{HSO}_4$, or acid sulphate of ethyl, consists of sulphuric acid, for one of whose replaceable hydrogen atoms the organic radical-ethyl, C_2H_5 , has been substituted. Sulphovinic acid may be prepared by heating a mixture of equal parts of strong sulphuric acid and absolute alcohol to about 212°F. , allowing it to stand for four hours, and then diluting the solution with water, and saturating it with barium carbonate, or as an alternative, lead carbonate. The excess of sulphuric acid is thereby precipitated as barium sulphate, and the filtrate which contains the barium salt of sulphovinic acid is then evaporated to crystallization. The crystals of barium-ethyl-sulphate thus obtained are redissolved in water, and the barium is removed by the addition of an exactly equivalent quantity of sulphuric acid, the filtrate from this operation being subsequently evaporated in a vacuum over a powerful drying agent, such as calcium chloride. Pure sulphovinic acid is a colorless, syrupy liquid, which mixes readily with water and with alcohol, but which is insoluble in ether. It is a strongly acidic substance, containing one atom of replaceable hydrogen; and it forms, with various bases a series of crystallizable salts which are all readily soluble in water. Its aqueous solution decomposes slowly in the cold; and when heated, it decomposes with the liberation of absolute free sulphuric acid. Its alcoholic solution when heated yields ether and sulphuric acid. It combines with the salts of various organic acids, with the formation of the corresponding ethyl ethers, or esters. Di-ethyl sulphate, $(\text{C}_2\text{H}_5)_2\text{SO}_4$, is a compound of this character, which is most conveniently prepared by slowly distilling absolute alcohol with concentrated sulphuric acid in a vacuum. The distillate separates into two layers, the lower of which consists of pure di-ethyl sulphate. It is an oily liquid with an odor resembling that of peppermint. It is insoluble in water, in which, however, it decomposes slowly. If di-ethyl sulphate is heated in water it decomposes rapidly into alcohol, sulphuric acid, and sulphovinic acid.
